

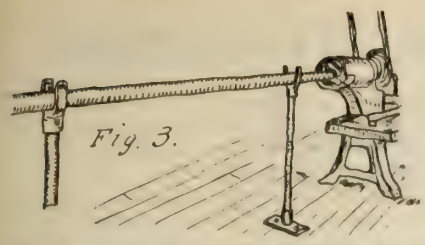

Fig. 3.—Pipe Guard for Confining Long Rods Projecting Beyond the Head Stock.

and it should be seen that these guards are kept in position while the lathes are running. If it is necessary to remove them for any reason, they should be replaced before starting the machines. There is present a very positive element of danger when an operator attempts to clean, oil, repair, or adjust machines while they are in motion. Shop rules should prohibit these practices. Sometimes a mechanic is seen leaning over the headstock of a lathe in an attempt to change the back gears before the machine has come to a stop. Some part of his clothing may be caught and drawn into the machine, which would cause serious injuries. Such practices are also very likely to do some damage to the lathe itself, quite apart from the risk taken by the operator.

Miscellaneous Suggestions

When attempting to remove filings and chips from a lathe it is always a good precaution to use a brush, because many severe cuts have been received when doing this work with the bare hands. It is not a good or safe practice to change clothes while standing near moving belts or machinery of any kind. Torn or ragged clothes, and unbuttoned or loose smocks or overalls all invite trouble. Machinists should not wear rings while working on a lathe. It is not only bad form but dangerous practice to leave tools lying about on the machines, especially in elevated places from where they may be jarred or pushed off. It is infiinitely better to place them in a tool box or rack provided for the purpose.

Many other causes of accidents could be mentioned, but the ones touched upon are responsible for the largest share of accidents. If the points refered to are noted and precautions taken to avoid the dangers pointed out, there is no doubt but that the safety and the efficiency of any shop will be greatly improved.

THE INDUSTRIAL DIAMOND

(Continued from page 23)

ing a smooth finished face, and are great labor savers.

A specified number of these diamond tee h are inserted in vee slots round the rim of the blade, and held securely by means of rivetted dowels. There are several designs of teeth, and some are made containing one, others containing two diamonds in each tooth. Others again, are filled along the cutting edge with small diamond splints, and are known as "splint teeth."

The setting of diamond teeth is somewhat technical, and is always done by firms specially equipped for this class of work. By one method, a deep hole is drilled in a piece of bar steel. A diamond is dropped into this hole, which is then closed up in an electric welding vise. This method has a disadvantage, inasmuch as the welded piece of steel has to be ground down until contact is made with the diamond, and there is grave risk of injury to the stone. There is also danger of overheating, and consequently spoiling the temper of the diamond. The diamond is not set on cutting edges by this method, which is not correct.

There has been improvement here also, and the "cast" process has been perfected in the making of diamond teeth. The alloy used is extremely hard, and has a low fusing point. This method also allows the diamond to be placed exactly, and with cutting edges exposed, and it is universally accepted as the correct and most efficient mounting. With regard to the running of these saws, care must be taken to see that the blade is hammered correctly to suit the 12,000 feet per min. periphery speed, so that it will run in a true vertical plane, free from gyroscopic action. There must be side motion of the spindle, and the more abundant supply of water there is directed into the cut, the better the teeth will cut.

Shocks and sudden blows on or near the rim of the blade must be avoided, and the feed speed not more than the diammonds will comfortably cut without forcing. This varies according to the kind of stone being negotiated. It is not commercially possible to cut granite with these saws. There are many other points in connection with this interesting work, which must be taken care of, but the above gives a general idea of the methods, and what is required.

There may be found in the future, other uses for the industrial diamond, for in these days of business courage and progress, anything towards economy in manufacturing will most assuredly be taken up. It is with this idea of economy that this article is written, and the handling of diamond tools is something every tool maker and machinist should know, in order that this costly commodity may be used to advantage, and be given the right to prove the value there is in it industrially, as well as it has hitherto done to establish itself as a thing of beauty for personal adornment.

INTERESTING NEW LAMP

A demonstration was given recently in England, by A. J. Elverson the inventor, of a newly designed lamp which makes machinery running at the highest possible speed appear to be running quite slowly, so that every movement it makes can be easily seen. The light is not continuous but flashes are emitted with a duration of about 1,000,000th of a second, so that the effect on the eye is a series of photographic impressions. The lamp is operated by a system of gearing.

OBITUARY

John H. Patterson, founder and chairman of the board of directors of the National Cash Register Co., Dayton, Ohio, died suddenly a few days ago while on a train bound for Atlantic City. Mr. Patterson has been failing in health lately, and the trip was being taken in the hopes of his recovery. Mr. Patterson will be missed not only in his own locality, but elsewhere as he was an earnest social worker, and has done much to increase the comfort and improve the working conditions for his employees.

CANADA'S WATER POWER

Canada comes second among the nations of the world in water development. The United States leads with developed horse power of 9,243,000 while in Canada electrical installations provide 2,470,580 h. p. annually. In Europe, France leads with 1,400,000 horsepower and other leading nations are: Norway, 1,350,000 h. p.; Sweden, 1,200,00 h. p.; Switzerland,; 1,070,000 h. p. Japan and India are the only two nations with more than 1,000,000 h. p. developed water power. Australia has practically none and New Zealand but 45,000 h. p. Norway has per capita water power development of 0.54 horse power and Canada comes second among the nations of the world with 0.26 h. p. In the United States the figure is 0.07 h. p.

BLOW TORCH OPERATES UNDER 10 FT. OF WATER

Interesting experiments have been carried out in connection with the operation of the oxy-acetylene torch under water. One of these was made recently in England, the diver working inside a huge circular tank filled with water. The tank is fitted with several plate-glass windows, which allow close examination of what is going on inside, the tank itself being internally illuminated. Equipped with a diving suit, complete with telephone apparatus, the diver could be heard acknowledging instructions that the oxy-acetylene apparatus was about to be lowered to him. From above several attendants worked the diving apparatus and the above-water end of the telephone, while a mechanic lit the oxy-acetylene flame from an ordinary candle. This submersible flame burned with an increasing roar as more power was turned on, the roar abruptly ceasing as the apparatus dipped below the surface to the waiting diver, who proceeded to demonstrate the possibilities of this new process, neatly applying the flame to a sheet of steel which reposed on two iron trestles. From the observation windows the illusion that the diver was doing salvage work on a sunken ship was heightened by his apparently awkward movements in the green cloudy water. The impression was left that this new invention will have a great future in salvage work on vessels sunk during the war which cannot be raised intact owing to present prohibitive costs.

Careful Tool Set-Up Assures Better Production

Automatic Machines Should be Kept in Good Condition—Operator Must See That All Settings Are Properly Made Before Starting Machine—Effective Feeding Reduces Unproductive Time

By DONALD A. HAMPSON

NEATNESS about a machine counts for a great deal in appearance, discipline and production. Floors about automatics need not be slippery with oil. Neither do they have to be covered with saw dust like a butcher shop. Proper splash plates, proper piping, and trained men can keep an automatic floor almost as dry as that in any other department. Oil on a wooden floor increases the fire risk. Oil will make a concrete floor crumble like clay in a few years' time.

An oil separator ought to be part of the smallest screw machine department. A machine of only moderate size will use a barrel of oil in two months, at least half of which can be recovered in a chip separator at no cost other than for power. An attendant has to remove the chips in any case—and it costs no more to remove them to a separator than to a dump.

In line with savings comes that of operators' time. Where there are machines enough to keep him busy, he should not remove chips and parts. That should be laborers' work. And the best time to remove it is out of running hours A night man can remove the afternoon's work and employees working during the noon hour can take away what has accumulated during the morning. It is even better to have the afternoon's product removed early the next morning, after it has had time to thoroughly drain. When kept busy, the operator should do no more than haul away work and chips that obstruct tool movements.

High spindle speeds are necesary for low production costs but high speeds mean throwing of oil. On Acmes, the writer has found it best to augment the front and back splash plates by a top plate resting on the other two. This is a floor protection and it assists the operator and set up men. No matter how nicely tools are set when feeding by hand, they always cut differently when power feed is applied and settings have to be made ultimately to conform with this. Threading to a shoulder in the third position is hard to see without getting splashed with oil but the top plate protects the workman from this, enabling him to observe action close to a shoulder near the spindle.

Removing Chucks

Chuck nose pieces are invariably drilled for a spanner, as are numerous other nuts on automatics. Now if there is one abortion in tools, the spanner is it. It is unmechanical, it is inefficient, it is an all around nuisance. Millions of holes and notches cry loudly of abuse, evidence that the spanner would not do what it was intended to do. Spanner slips, knuckles skinned, workman swears, hammer and chisel applied, hole ruined. That is the story of the spanner nut every time.

We found that a great deal of time was lost on our automatics from this "tool." Two conscientious men would work an hour getting off the nose pieces from a four spindle machine that hadn't been changed for a year; they would try in vain to block the spindles or hold the belt while one man would hold some miserable patented spanner in place for the other to strike with a hammer. (Punches and chisels were forbidden on the machines). Finally we gathered all the spanners together, wrapped them up, and gave them to the sweeper with instructions to carry the package down the street to the bridge and drop it in the river.

Then we made the simple tool illustrated by Fig. 4. The teat fits the hole and the long end comes out where a man can strike it conveniently with a hammer. We have no more spanner trouble, we have no holes bruised up, we now do in three minutes what used to take two hours to do. Away with the spanner! A plain pin or turning with the fingers will move any spanner nut after it is started off and will bring it up to its shoulder, going on. One light tap on our tool, either way, does all the hard work.

Something About Tools

The tools supplied by manufacturers are so well designed and of such a wide assortment that it does not pay to make them in the shop. Stock tools will do everything but special operations or work beyond the capacity of a machine. There are some tools, like box mills. that are not made with a set screw back of the cutter to take the thrust. On a heavy cut, this metal-to-metal contact does not hold well; a simple way to increase the friction is to place a narrow strip of emery cloth between the cutter and the hardened body of the mill.

Under heavy cuts, the set screws or binder screws used in various tools or in the turrets do not hold—and the tools slip with attendant troubles and stoppage. Stock wrenches are supplied for these positions but they are designed and seletced for the strong man—when a person of slighter build works on the machine, it is advisable (and permissible) to permit them to use wrenches of a larger size in order to keep their machines going to capacity.

Reference to Fig. 5 will show how a die head may be secured from changing position when pulling hard, and secured without straining any parts. A split block is bored to fit the stem and tap bolts put in. One half has projecting lugs that reach over the cylinder. It is a slip-proof arrangement and very cheaply made. The coarsest thread may be cut without the die moving the least bit.

When the number of tool positions is limited and the number of cuts many, auxiliary tools must be arranged. A tool for pointing the ends of blanks is shown by Fig. 6. It is placed within the body of an ordinary box mill. Three pieces of drawn steel, some screws, and a cutter make up this tool. The larger piece fits in the mill opening and is clamped at the ends—also adjustable for length in this manner. The cutter is a tangential tool and is well backed up. Facing tools could be created from the same design.

There is one drawback to wire feeding in a screw machine. Where the bar is large and the feed long, the inertia

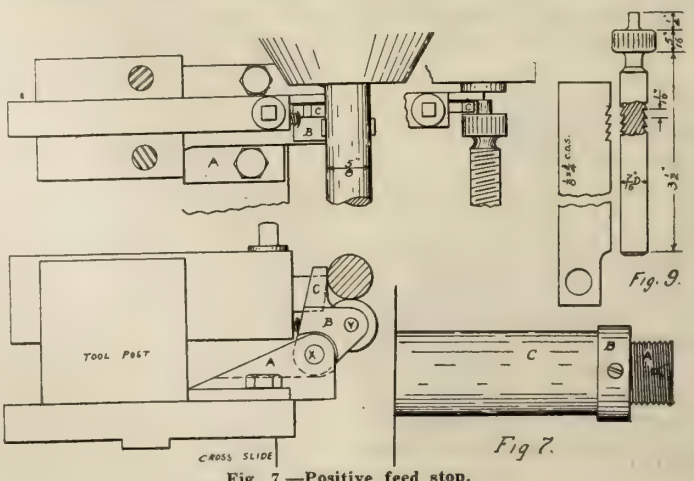

Fig. 7.—Positive feed stop.
Fig. 9.—Buttress screw details.

The first part of this article appeared in May 4 issue.

acquired during the forward movement is considerable and the bar, instead of being innocently fed up, becomes a battering ram. A stop held by friction only cannot resist this force. Fig. 7 is a positive feed stop. The regular stop is the part A, which here has been threaded and fitted with B a round nut (hand fitted by the way), and supplied with pieces of pipe C in lengths to suit the job. The use of such a top eliminates one more of the sources of trouble common to automatics.

Difficult Screw Product

Figs. 8 and 9 show how a rather difficult piece is being turned out on a 7-8 in. Cleveland. The work, a buttress treaded screw is shown by Fig. 9, reference to which will show that there is considerable work on the piece. In view of the fact that the machine doing this work is a Model C—a type with but three positions in the tool cylinder—the production of these screws is 5 in. over all, the shortest is 1½ in. over all, the difference being in the length of threaded body. Th longest screws are made at the rate of 16 per hour.

Buttress threads are about as difficult to produce as any shape and when the diameter of the piece is small as compared to the lead, there is present the same trouble found in cutting square threads, i. e., that of a heavy cut which nearly twists the piece from the bar. The buttress thread has also an inherent source of trouble in not being a symmetrical thread, as are other familiar threads; there is a constant tendency for the sloping side to crawl back, leaving the load side at other than right angles to the axis. In the service for which these screws are used, a variation of one-quarter thread in a length of two-inches condemns the piece.

At the plant where these screws are used, they used to buy them of big specialists. Then, it was a common sight to see a keg full being headed up for the return trip—condemned because of roughness or faulty lead. The shop people did not underrate the difficulties a bit but when this Cleveland automatic became available after a long run on war work they decided to make them at home and have the difficulties under their own roof instead of a thousand miles away. And during the first few weeks, the difficulties appeared in profusion.

Knurling Device

Some idea of the set-up may be gained from the photo. All went well during the first year, when a knurl was decided upon for the head. Some sort of knurling device had to be provided that would work on all lengths of screw, which was something of a problem as there was no extra tool position, no chance for a center tool between the three, no room to index the tools if a knurler was added ahead of the box mill.

Fig. 8 shows the arrangement adopted for knurling. It is applied to the front, or cut off, tool slide and works in connection with the cross slide tools. A is the body casting, B a tool steel piece pivoted at X and holding a knurling wheel on the pin Y while there is an arm C extending upward on the side toward the cut-off holder. It is evident that a forward movement of the tool slide will bring the arm portion in contact with the bar stock and further movement cause it to swing about X and imbed the knurling wheel in the bar, but not at the same spot as touched by the arm, for which see the plan view.

Knurling is done while the cut-off tool is near the bar and immediately after the chuck has closed on the newly fed bar. Then the tool recedes and the body is box milled and threaded. As the die is drawing off, the forming tool is approaching from the rear and it forms the head, neck, and teat at the inner end. Finally the cutting off tool advances a second time, this time to sever the piece. All the time the tool post is carrying the knurling unit. But

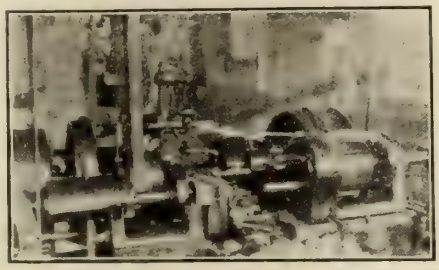

Fig. 8.—Cutting buttress screws on Cleveland Automatic.

in this last move, the arm C does not encounter the bar for that section was cut away in forming the teat and the arm occupies the space, as seen by the upper right hand view.

Coarse Straight Knurl

A very coarse straight knurl was desired. To roll this in with a single tool and in the limited time allowed by the other tool positions exerted a tremendous extra load on the front spindle bearing cap. These are lined with a renewable white metal bushing but after replacing a couple the scheme shown by Fig. 11 was adopted to relieve the bearing of some load. This consists of a U shaped steel casting secured to the front face of the headstock and carrying inside the U a bronde shoe which bears against the projecting front end of the spindle. This arrangement worked very well and proved a decided aid in prolonging the life of bearings.

This same plant turns out other buttress threads of more or less "tricky" design. It was anticipated that the die would not maintain any kind of a satisfactory lead unless backed up by a cam—and trial proved this to be true. Carefully made cams follow the die on all these threads. Even then the thread will vary or will start badly. Some means of compensation has to be provided and on some parts it is necessary to make the piece longer than required so that the poor thread may be cut off.

Buttress threads are successfully produced on the Acme as well as those on the Cleveland. Recently the writer saw an Acme working in a buttress thread, cutting it with a Namco round adjustable die while nearby was the Cleveland making the screw before described and threading it with a Modern self opening die.

Spindle Stopping Kink

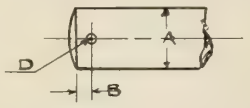
Acme automatics have a spindle stopping device which throws out a friction clutch and while it is out dogs on a spindle member engage a stop piece which prevents the spindle from turning while the die is being run on at the other end. When the thread is cut, the clutch re-engages and the dogs revolve clear of the stop piece. There should be plenty of room between piece and dogs when running and ample engaging surface when threading but, due to neglect or lack of knowledge of the trouble, many operators worry along with the contact ends of these parts rounded over badly and working in a very unsatisfactory manner. The remedy is to renew the pins and rollers—two each—on the clutch throw-out. It is simple when one knows the cause of the trouble. Sometimes it is better to make the rollers oversize and gain additional movement. This point has been a valuable aid to many men who were complaining of the Acme scheme of threading.

Better Records

In Canadian Machinery of Dec. 9, 1920, Mr. Scriber took up the matter of better and more efficient records for automatic machine tools. This may apply with full force to screw machine automatics. The writer has found some of the blanks supplied by makers and the charts in instruction books to be almost a detriment because their notations were not direct enough. He has found it better to disregard the forms in part and depend upon dimensioned sketches of the tool settings and cam drums. In the matter of gear trains, he has lettered the gear positions in the diagrams and the charts and found that method far superior to the "driver and driven"—"back shaft and front shaft" scheme of notation. A set-up record should be plain on its face, evident at once in all points to the man who has'nt touched the machine for a year or one who has attempted to set it up for the first time.

Let no one suppose that screw machine work is all trouble. True, "for ways that are dark and tricks that are vain," the automatic has the heathen Chinese beaten a mile, but it is interesting work and work that demands a high degree of skill to master in its several branches. It is a wonderful trade in itself. Let no one seek to belittle the all around screw machine man.

Among the interesting articles which will appear in forthcoming issues are the following: Proper Piling of Goods Reduces Costs, May 18; Saving Money By Means of the Turret Lathe, May 25; Punch Presses and What They Can Accomplish, June 1; Machine Shop Problems of Interest, June 8.



Practical Ideas for Shop Executives

STANDARD COTTER PIN SIZES

By Robert Mawson

Most machine shops design their small details in a very haphazard manner, the larger elements are given some thought and rightly so, but the smaller onsidered very insignificant and when these go into the shop to be made there is no system observed, the result being that the work is costly and unsatisfactory when viewed in the light of modern manufacture.

One of these glaring examples is the simple round stud or pin in which a hole is drilled for a cotter pin. Each draftsman has a different idea as to the size of cotter pin to use and also how far the hole should be drilled from the end of the piece. The result is that a variety of jigs are often provided for the same diameter of pin entailing different bushings and as naturally follows increased expense of manufacture.

A	COTTER PIN	B	D
UP TO 1/2	1/16 x 3/4	1/8	.48-.076
1/2 TO 9/16	3/32 x 1"	3/16	.36-.1065
5/8 TO 3/4	1/8 x 1 1/4	3/16	.27-.144
7/8 TO 1 3/16	3/16 x 1 1/2-2"	1/4	.9-.196
1 1/4 UP	1/4 x 2-2 1/2-3	1/4	13/64

Standard cotter pin sizes.

We resently prepared the list of standards for pin holes and cotter pins as illustrated in the drawing and it has proved itself very useful both in the engineering department, and also in the shop. By its use the draftsman knows exactly what size to call for on each drawing and when the design finally reaches the shop the machinist has also the necessary information to complete the job without asking any unnecessary questions which always means a loss of valuable time.

The first column A shows the diameter of pin to be drilled; for example 5/8 to 3/4 inch, in each case the sizes being inclusive. The second column is the diameter and length of cotter pins to be used in the piece, in the example taken this is 1/8 in. dia. and 1 1/4 in. in length. For the last two sizes in the tables there are a number of lengths given; this is necessary to provide for the diameters of pins in question, the diameter of cotter pin however being constant between the diameters of pin to be drilled as given in the table.

The third column marked B is the distance the hole is drilled from the end of the pin and is self-explanatory. The fourth or last column is the size of hole to be drilled or the diameter of drill to be used, the size for the example taken being therefore No. 27 which is .144 of an inch. It might be said that this table could be expanded to suit the various requirements of any machine shop, the one given being adequate for our shop however.

POSITIVE STOPS FOR TWIST DRILLS

By Harry Moore

Twist drills offer a very poor surface when it is a question of holding a stop collar on the fluted portion, and whether a screw be used, for tightening purposes, bearing direct on the drill, or whether a split collar is clamped thereon, the result is generally the same unless some means is used to back up the stop to prevent it slipping back under pressure. Whether a stop should be used, apart from the regular one on the machine, depends of course on the nature of the work, but in all cases where the face of the work differs in relation to the distance from the machine stop, some sort of a device on the drill itself must be used. Any method or means to obtain this must be positive in its action and therefore the examples of stops to be described will perhaps be of interest as each one contains this very essential feature.

The first example shows a special holder for use on turrets and screw machine work, which is specially adapted for use when drills have to be fed in but a short distance. In such cases there is ample room for a collar and the one shown in the drawing A, is held to the drill lightly by a setscrew and backed up by two knurled head screws B sliding in clear holes in the holder, these being held to their adjustment by hexagon nuts C resting against the face of holder. To obtain a positive stop the drill must always be pushed to the back of the hole before tightening. The holder shown at Fig. 2 is for a purpose directly opposite to the first; that is for drills which have to be fed in to a good depth, which consequently leaves very little room for collars or the like. The shank of holder fits the turret as usual, and the front end is drilled out for the largest size drill likely to be used, the top of the holder being milled away, as shown, to expose the drill. The adjusting screw A has a series of holes drilled in the head, and this member works in a tapped piece B which is driven snugly to the bottom of drill hole, the hole in the shank C being clear. This method of construction was necessary as the position from either end was too distant to permit the use of a standard length tap. The front of the holder is the actual stop for the work to come against, the drill being set to the required depth and backed up by screw A which is moved by inserting a piece of wire in the holes. Different size drills are taken care of in both holders by the use of bushes.

When a stop is required in a hurry it can be made as shown at Fig. 3, though this kind is not recommended as a permanent device. After the drill is pushed to the back of the hole, a strip of sheet metal the correct width is cut and bent round, both ends being pinched together with a pair of pliers, after which a slot is filed out to take a screw a nut to tighten it onto the drill, the flattened ends being chamfered off as shown at A. When the size of drill allows, the idea shown at Fig 4 is handy in all cases where a stop is to be kept permanently on the drill for use on one particular job. A small hole is drilled through the shank and a stud slipped in with a nut on both ends. The stop A is a piece of tubing with a slot filed in the top to suit the stud B, so that when the drill is ground on the end, this slot

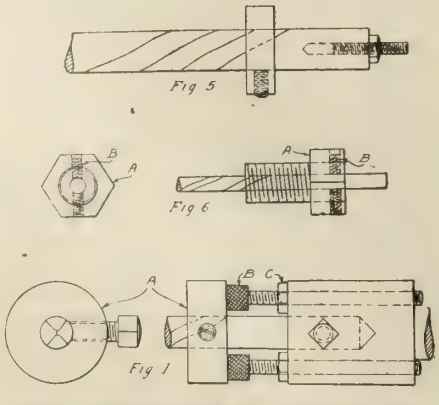


Fig. 1.—Drill stop for use on turrets and screw machines.
Fig. 5.—Collar and nut stop.
Fig. 6.—Quickly made stop.

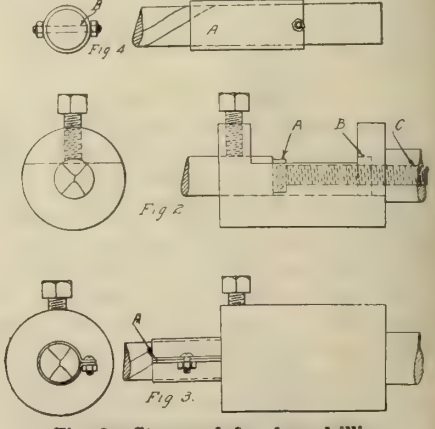

Fig. 2.—Stop used for deep drilling.
Fig. 3.—Emergency drill stop.
Fig. 4.—Permanent drill stop.

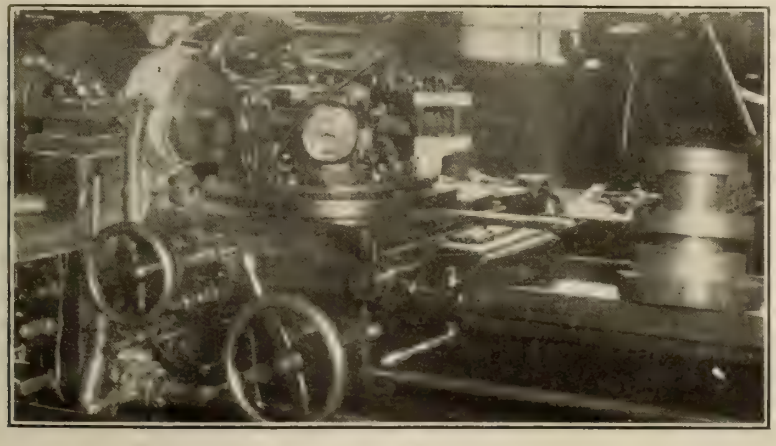
can be easily filed on the bottom to equalize the distance.

In Fig. 5 a collar is used together with a nut and screw, the latter fitting a clear hole in the end of drill. In this case the collar is backed up by the end of chuck jaws, and the drill by the end of the hole in chuck, the necessary adjustment being obtained by the nut and screw, which in effect lengthens or shortens the drill. A one-inch hexagon nut is handy for obtaining a quick stop for various sizes of drills. Tap the nut A as shown in Fig. 6, on each side, for 3/16 in. headless screws B, then all that is necessary is to drill out an old bolt with the drill to be used, and cut off the required length. Screw this into the nut until it touches the screws B, then slip the whole thing on the drill and tighten by means of screws B. As in the former case the back of the drill is supported by the chuck and the nut by the chuck jaws. The same nut, of course can be used for various sizes of drills.

THE DESIGNER AS A COST PRODUCER

By I. N. B.

The designer is often classed as a non-producer in spite of the fact that he may be, and often is, one of the greatest producers in the plant, measured by his ability to increase production. A certain shop had a number of complicated machines to build, the original machine was built by the inventor who was a fairly good mechanic but lacked the technical ability to lay out the machine along general engineering lines. The first machine was constructed by the cut and try method and proved a success when completed. He had notes and sketches that only he understood and he was engaged by the concern to make the duplicate machines. Two months was the time allowed for the production of the first machine. Six months has elapsed and the first machine is not yet completed, and part after part is made and discarded and the cost has run into figures that are seriously embarrassing the company for capital. As soon as the first machine is completed and is working as good as the original model there is plenty of capital available.



If a capable designer had been put on the job and made a complete set of working drawings the machine would have been finished and at cost within the prescribed limits. A bill of material would have been made out, and all the material could have been ordered and been on hand instead of shortage constantly occurring. The work could have been laid out in an efficient manner and furnished to the assemblers to keep them busy instead of having to wait for parts as they often have to do now. If the present man in charge was to die or even take sick it would be necessary to stop the work until a new man could become familiar with the original machine. Furthermore if a change is required it can be demonstrated on paper, interferences discovered and eliminated, changes made and the only cost involved would be the cost of paper and the time of one or two men. In the present case a change often means the holding up of five or six men and the piece discarded or used in such a a condition as to cause a break down when the machine is finished.

As an example of the value of a designer one has only to look at the high efficiency of the strops producing for automobiles. Take the vertical automatic lathe in the Nash Motors Co. shops that finishes turning and boring both sides of a flywheel in about seven and a half minutes. Imagine building a machine of that kind on the lines mentioned and yet the aforesaid machine is required to do more than five different classes of work while the lathe is only required to do two. Of course all well regulated concerns employ a designer but many smaller shops might find it would pay them to do so if only for a short time, even if they had to pay a premium on the short time employed.

HEAVY TURRET LATHE JOB

By Henry James

In the manufacture of their geared head lathes the Greaves, Klusman Co., require gears of flawless metal, and for this reason it is necessary that they machine from a large rough forging. The illustration shows a Cincinnati Acme universal turret lathe machining these chrome nickel steel forgings into rough turned gear blanks. The piece is chucked on outside diameter. An ordinary lathe tool is held in the flat turret and used to face the end. A centering tool is held in the flat turret and used for centering, so that a cone centre can be used to securely support the work. The tools held in the square turret are used to turn the various diameters and necks. The next operation is to drill, bore, ream, turn and face the opposite end. The metal removed in the two operations is 162 lbs., the rough forging weighing 275 lbs. The production time on each piece is approximately 1 hour and 15 minutes.

Machining chrome nickel gear blanks.

REMOVAL OF SCRAP

By R. V. Williams

A means for labor saving which has been worked out at the works of the Stearns Rogers Co., is inexpensive and simple in design, as well as possible for application in a wide range of plants. At this plant metal chips and turnings are gathered together on an elevated platform just outside the main building. When a carload of this scrap has been accumulated, a freight car is set in and scrap is loaded by hand from the platform.

All this scrap must be hauled from the plant to the platform—a distance of 30 feet—and raised to the platform by hand. Wheelbarrows are used for this purpose, and to make it possible for the workmen to push the barrows up to the platform level without an incline of excessive length, a piece of 4-inch channel iron has been built in the center of the incline walk. Cleats are nailed along the incline on each side of the channel. This metal track offers little resistance to the wheel of the barrow, and since there is a channel form, the workman need not bother about direction; he can put all his effort into raising the load.

Two other arrangements have minimized the labor necessary to handle the scrap. One of these is the covering of the platform floor with scraps of boiler plate to facilitate shoveling; the other is to have the top of the retaining wall about the platform just level with the top of the standard gondola freight car.

Experiments conducted during the war showed that aluminum could be obtained not only from pure clay, but from many inferior grades subjected to certain treatment. As a consequence the aluminum industry has been developed extensively in southern Germany where hydro-electric power is used in its production. Prior to the war the output of aluminum amounted to around 800 metric tons annually, while it is now about 32,800 metric tons.

Technically Trained Men Make Good Salesmen

Opportunities as Great on Distribution Side as That of Production—Salesmanship To-day Must be Backed With the Ability to Give Service—The Engineer Drummer

ONCE upon a time the effective salesman was a man who knew a lot of good stories and understood how to entertain the buyers. He got orders because he was a good scout. That's the way it used to be. But effective selling is not done that way any more. A new type of salesman has risen....a man whose most valuable asset is his knowledge. A salesman these days must know his product. He must know how it was made and what materials were put into it, and he must possess the same knowledge of the articles against which he is competing. He must know how the thing he is selling can be used most effectively, and he must tell his customers how to get the maximum value out of it. Of course, appearance and personality still count for something. A successful salesman still has to make a favorable personal impression on his prospective customers. But mere good fellowship is no longer sufficient. It must be backed with the ability to give service, says the Industrial Digest.

Technically trained men in fast increasing numbers are taking selling jobs during these days. An engineering training used to be considered a preparation for a job on the production of industry only, but now many engineers are joining the sales force. There's more money for them right away in selling than in the usual engineer's job. And they are making good as salesmen.

"From conversations with employers, and from a general discussion of the subject, I am convinced that there is a greater demand now than formerly for men with engineering training in the sales department," said George B. Pegram, dean of the Columbia University schools of engineering. "I have no statistics upon which to base this opinion, but I believe it to be true. Business has developed in such a manner that technical training is absolutely necessary to a man who wants to sell certain kinds of goods.

"For instance, it is hard to see how the General Electric Co., could sell its goods at all without the aid of men with technical knowledge. The same thing is true of all concerns which deal in machinery. A man buys a machine because he thinks it will be the most economical means of obtaining the results he wants. Since the determination of the most economical methods of obtaining a given result is an engineering problem, it is natural that engineers are well equipped to sell goods that are bought on that basis."

Prestige Sustained

Dean Pegram was asked if he thought that an engineer loses any of his professional standing when he becomes a salesman:—"No. Selling is just as professional as any other branch of engineering," he replied. "Salesmanship is a field in which a man can display all the high qualities of an engineer. A good engineer-salesman will co-operate with his customers and not try to put something over on them. He will sell them the goods they really need, instead of unloading his inferior stocks on them. And, as business is done today, there is room for such a man to succeed."

The best field for the technically trained salesman is, of course, a field in which the product is used by other technical men for technical purposes. An engineer is naturally adapted to sell such things as electrical goods, machinery, chemicals, and steel products. But the new type of salesman is not confined to these lines. He is appearing in all trades; selling socks, office specialties, and even ladies' waists.

"A technical training is useful to a salesman in almost any line today," said a young engineer who has made a success of selling ladies' hosiery, "because the modern salesman has to know how his product was made. Most prospects tell you, these days, that your prices are too high. One of the most effective ways to meet an argument of that kind is to explain just what items entered into the manufacture of your product, and show the prospect that your article really costs a great deal to make. He can go into great detail about processes of manufacture while the prospect listens open-mouthed, and frequently this ability enables him to come home with the order.

The New Conscience

"Now suppose an engineer runs into a situation like this: He is trying to sell a corporation a piece of machinery, and his competitor is offering something that he knows will fill the bill just a little bit better than his machine. What ought he to do? A salesman pure and simple, will point out the advantages of his own article, and let the other fellow point out the advantages of his. If the customer makes a mistake and chooses the wrong machine, that isn't the salesman's fault. His business is to sell machines, not to guide his customers along the most efficient path.

"An engineer-salesman, placed in a position like that, would be likely to hesitate before urging his customer too closely to buy a machine that was not the best solution for his problem. The technically trained man has been taught to look at such a situation as a problem in engineering, not in salesmanship. So he would be tempted to slow down on his selling talk, and perhaps the other fellow would get the sale."

The National Council of Traveling Salesman's Associations, the spokesman organization for 500,000 commercial road men, is preparing to fortify the members of the twenty-eight bodies affiliated with it with technical information on the merchandise they are selling.

Herbert L. Schamberg, managing director of the National Council, in discussing this plan, agreed that the popularly pictured type of drummer is rapidly passing out of the business picture. "I believe that the growing sharpness of competition makes selling along more scientific lines absolutely necessary. We have found that in a selective market, such as prevailing to-day, bluff good fellowship is becoming a drug on the market. The retailer, for example, is serious these days. He knows that the consumer has a pair of hawk eyes fastened on values and that the funniest story in the world won't sell a pair of shoes for six dollars when somebody else is selling them for five. The salesman must be able to show the retailer that he is giving him real value, and the only way he can clearly discuss his product is by learning all about it himself.

"One factor that enters into the supplanting of the old type of salesmanship is the fact that the men of the new school are more studiously inclined. For the most part they are better educated. Their minds are trained for analyses. The old school salesman usually worked up from the stock boy or office boy. There were few schools in salesmanship. College trained men seldom took to selling on the road.

"The National Council is prepared to lend its assistance in equipping salesmen with technical information on the merchandise they are purveying."

MAKING OF SMALL TOOLS

Although Great Britain was the pioneer engineerinng country and its manufacturers cover practically every section of enterprise, there were one or two directions in which, for reasons which are a little obscure, British engineering firms did not trouble themselves at one time to give much attention. One of the most curious instances is in the range of small tools required by engineers. Among these tools are various kinds of callipers, squares, gauges, etc. Arrangements have now been made, however, for turning out in a British factory a complete range of all these necessary accessories. A factory which was erected during the war for the purpose of making magnetos has been adapted for the manufacture of these small tools; and already a very extensive range of extremely accurate and well-made appliances has been turned out.

New Things in Shop Equipment

ADJUSTABLE TEMPLET THREAD GAUGES

An adjustable templet thread gauge of the ring type, in which the threaded hole is located eccentrically relative to the periphery, has recently been placed on the market. The ring is slotted completely through at a point where the ring wall is widest. The gauge is adjusted by tightening up a screw placed perpendicularly to the split ends of the gauge. A hardened drill-rod pin keeps the gauge from twisting. The gauge is made in all sizes from 3/16 of an inch up, and in all standard, as well as many special, threads. The manufacturers are the Superior Thread Gauge Manufacturing Co. of Brooklyn, N. Y.

ELECTRIC-DRIVEN GAS FURNACE BLAST

There is now being placed on the market an electrically operated blast intended for application to gas furnaces for regulating the mixture of air and gas delivered to the furnace. The blast is driven by a one sixth horsepower universal motor and delivers 210 cu. ft. of air per minute, at a motor speed of 10,000 r. p. m. Current for the motor may be taken from any lighting socket. The device functions somewhat similar to that of an automobile carburetor. The mixture of air and gas should be rich until the furnace has been warmed up, after which a damper on the blast adjacent to the blower, should be gradually opened to admit more air. The blast is not dependent on a normal gas pressure, a sufficient amount of gas is drawn from the mains to heat a furnace without variation. The apparatus offers a convenient means of heating a furnace after regular working hours. It is marketed under the trade name of "Cadillac". It is manufactured by the Clements Mfg. Co. of Chicago, Ill.

SCREW PLATE SET

A very useful screw plate set, complete in an attractive well-finished box has recently been placed on the market. All the dies of the set are hexagonal. The die-stock is made of an aluminum alloy and the tap wrench is made of steel, with hollow handles to reduce its weight. The dies are made adjustable by splitting one side and providing a filister head screw for drawing the split ends together. An ordinary wrench may be used to turn the dies instead of the stock. Such provision is often convenient when working in cramped places. The dies are of standard form and chip clearance, and are intended to cut full and perfect threads. A hexagonal adapter furnished with the set provides for holding dies that are small in outside diameter in the same stock. Attached to the stock by means of knurled-head screws is an adjustable guide which may be swung to one side to permit the changing of dies after the screws have been loosened. When tightened again the screws hold the guide in position over the centre of the die and lock the jaws of the guide so that they will not move while threading a number of pieces of one size. The cutting faces of the die are formed by broaching. In this way a correct shape is produced and an equal distance maintained between all cutting lands. The set is made with both the U. S. standard and the S. A. E. forms of thread. The set is manufactured by the Frank O. Wells Co., Inc. of Greenfield, Mass.

LAPPING AND FILING LATHE HEAD

In order to provide for lapping and filing small work without tying up expensive equipment there has recently been placed on the market a lapping and filing head. In the head a spindle is supported, which is mounted on ball bearings. The drive is through an overhanging pulley on one end of the spindle, and is direct. On the other end of the spindle there is mounted either a Casler twin screw drill chuck or a three-jaw chuck. A belt guard can be readily attached to the head casting. The base of the casting is 10¾ in. and the distance between the pulleys and the chuck is 14¾ in. The head is manufactured by the Marvin & Casler Co. of Canastota, N. Y.

BALL BEARING HANGER

A simplified and improved design of ball-bearing hanger with a two point suspension for the bearing box has recently been placed on the market. The self-aligning ball-bearing incorporated in the older types of hangers is accommodated in the new type. The bearing is contained in a split housing rigidly held by two suspension rods. The arrangement is one that is very compact, is easily assembled, located or inspected. Vertical or horizontal adjustments can readily be made, at the end of the housing by means of lock-nuts and set-screws. This does away with the possibility of applying pressure to the bearing while making adjustments. The self-aligning feature of the bearing allows the shaft to turn freely at all times, with a minimum of friction and heating. A shaft which is long can be assembled on the floor with the bearings placed at the proper intervals and in plain view and it then can be raised into position for final adjustment with bearing caps off. The hanger is manufactured by the S. K. F. Industries Inc. of New York City.

PORTABLE SAW BENCH

Rather unique in the field of portable tools for the pattern-shop is the universal saw bench, mounted on a pedestal on rollers, which has recently been placed on the market. The saw is driven by a half horse-power motor and is capable of handling stock up to 2 in. thick. The table can be locked in place at any angle up to 45 deg., a graduated dial to indicate the angle being provided. The cross cut gauge may be used on either side of the saw and can be quickly set and clamped in position. The ripping gauge may also be used on either side of the saw. This gauge is automatically lined up with the saw when locked in position. The saw is seven inches in diameter and may be of the ripping crosscut type or a combination of the two. A splitter guard is provided to keep the stock from pinching in the saw. The height of the saw above the table surface may be adjusted as the saw arbor is hinged for this purpose. The pedestal has two rollers at the back. At the front there are located two legs that firmly hold the machine when in operation. Between these two legs is mounted an elevating roller mounted on a swivel and connected to a tongue or draw bar. This roller is lowered and the feet at the front are raised when it is desired to move the machine. The saw bench is manufactured by the Union Machine Co., of Grand Rapids, Mich.

DIE-FILING MACHINE

A small size die-filing machine which may be mounted on a bench, or on a pedestal having elevating rollers has been placed on the market recently. When the elevating rollers are lowered and the pedestal raised, the machine can be conveniently moved about the shop. When it is located where it is desired to use the machine, the base of the pedestal forms a solid foundation when the rollers are again raised. The machine is electric driven and current can be taken from any lighting socket. A one-eighth horsepower, 1,720 r. p. m., motor is provided which is fully enclosed in a sheet metal case. The file is operated through a ram which is driven by a crank and connecting rod. By adjusting the throw of the crank it is possible to obtain any length of stroke up to three inches. The length of the connecting rod can also be adjusted to bring the working section of the file into any desired position relative to the work. Speeds of 200, 300 and 400 strokes per minute can be obtained through a cone pulley. The work table is pivoted on a yoke to enable various degrees of clearance to be filed in a die.

This yoke is in turn pivoted on the frame of the machine. A graduated dial is provided for each of these pivoted supports, which feature facilitates rapid and accurate setting of the table, to any desired clearance angle. There is an outboard support for the file and standard or special files can be used. The height of the table is convenient for a man sitting on a stool. The table is 12 in. square. The weight of the machine is about 80 pounds. It is manufactured by W. D. Rearwin of Grand Rapids, Mich.

AUTOMATIC MIXING AIR-GAS INSPIRATOR

There has been recently placed on the market a new type of low pressure air-gas inspirator. The original design was intended to be used on a certain type of furnace. The new design is, however, applicable to all other makes of furnaces. The entire operation of a furnace equipped with this device is controlled through one valve. The mixture of gas and air is always constant, that is to say that an increase or decrease in the air supply automatically causes the amount of gas delivered to be increased or decreased proportionately. The gas cock is operated only when starting or stopping the furnace, and therefore is always in either the "full on" or "off" positions. It is claimed that no explosive mixtures are possible in any part of the distributing mains as the gas and air are mixed only at the point of supply to the burners. The advantages claimed are an automatic supply of air and gas in the desired proportions under all conditions, through mixing of the air and gas just prior to entering the furnace, and an instantaneous combustion. The inspirator is manufactured by the Surface Combustion Co. of New York city.

PATTERNMAKER'S LATHE

There has recently been placed on the market a motor driven patternmaker's lathe built in sizes of 16, 20, or 24 in. swing. The lathes are supplied in standard bed lengths of eight and ten feet. A somewhat unusual feature is one that permits the headstock to be swung about five degrees each side of the centre to provide for turning tapers. For the accommodation of face plates the spindle is threaded on the outer end as well as on the inner and usual place. Radial loads and the end thrust of the spindle are taken by double-row self-aligning ball bearings. The open side type of tailstock is provided. For turning tapers the tailstock may also be set over. A compound rest is provided with complete graduations, which permits quick settings to be made at various angles. Power feed is regularly furnished to the carriage and in addition a hand feed can also be provided. Where power feed is provided it is controlled by a friction knob on the apron, and reverse can be obtained by operating a lever. A two horsepower motor, mounted on an adjustable base and direct connected to a four-step cone pulley, is located on the under side of the bed directly under the head. The adjustable feature of the bed allows for belt adjustment. Belt shifters and a control box are conveniently located. A brake lever, operating on the inside of the cone pulley on the spindle instantly stops the rotation of the spindle when the power is shut off. If desired the machine may be equipped with a countershaft drive. The manufacturers are The Imperial Metal Products Co., of Grand Rapids, Mich.

UNIVERSAL ANGLE FIXTURE

A very useful fixture for tool room jobs, where it is necessary to hold the work in angular positions while being machined, has been recently placed on the market. The device has a work-holding plate which may be swivelled 90 degrees, on either side of the horizontal plane, and which may also be revolved around an entire circle. Graduated dials are provided to facilitate settings. All surfaces of the plate are ground square with each other and this member has a series of holes which provide for the quick clamping of work by means of patented clamps. The plate hinges about a ¾ in. stud which is threaded on one end, and is used to clamp the plate in desired positions about the horizontal plane. Large flanges on the plate engage in desired positions about the horizontal plane. Large flanges on the plate engage the faces of bosses on the yoke lugs which provide sufficient friction to hold the plate secure under all conditions. The yoke casting revolves on 1½ in. pilot at the centre of the base. The yoke casting is secured by two half inch bolts which ride in a circular T-slot machined in the base. The size of the fixture plate holding surface is 3⅜ by 4¾ in.

The weight of the fixture is twenty-five pounds. The manufacturers are E. L. Krag and Co., of Chicago, Ill. It is marketed under the trade name of "Little Bob."

"SIMPLEX" ELECTRIC SAFETY STOP

There has recently been placed on the market a stop that is used to obtain instantaneous operation of a clutch or to shift a belt, on various types of automatic machines in the event that the stock is oversize, undersize, overfed, or underfed, or in the case of some other irregularity. It is electrically operated and is intended for use on a lighting circuit although it can also be operated on a battery or generator circuit. On a blanking press the stop is mounted on the foot treadle rod, a latch on the stop engaging a notch in this rod. When the stop operates, the latch is disengaged stop operates, the latch is disengaged from the notch and the rod is forced forward by a spring. A small spring lever is also arranged to bear on the blanked scrap as the latter is fed from the die. When the scrap has been fed the desired amount, the lever rests on the metal between the blanked holes and while thus positioned the circuit is open. However, if the scrap is overfed or underfed the lever will extend into one of the blanked holes and the circuit will be closed. This will cause the stop to function and stop the operation of the machine. In this way injury to a die, as a result of punching the metal at a point where it has already been partially blanked out, is avoided. Wires may be run from the stop to contact points located on a machine wherever trouble is likely to happen. The pressure of the clutch or belt shifter rod against the stop-latch is reduced by means of two levers of unequal length. A spring for exerting pressure up to 75 lbs. may be used in connection with the stop. This spring is ample for shifting a 6 inch belt. The stop may be operated at any time by means of a hand-trip. The device may be so arranged that it will not interfere with the ordinary method of stopping and starting the machine. It is manufactured by the Atlantic Co. of Brooklyn, N. Y.

SPRING CUSHION FOR PUNCH PRESSES

There has recently been developed an even-pressure spring cushion for use when drawing shells on punch presses. It is claimed that the pressure on the draw ring is reduced by the use of the fixture. Wrinkles in work are completely eliminated, it is stated. The device has been designed for small and medium sized presses, where one of the necessary conditions is that it can be quickly and easily attached and detached from a press. It had been so designed that it is unnecessary to provide holes in the machine for attaching it. The cushion is simply held in place by screwing the upper threaded end of the suspension bolt, into a trapped hole in the bottom of the die or bolster plate. The suspension bolt extends through a sleeve having teeth cut on its outer surface near the upper end which are engaged on opposite sides by the teeth of two compensating cams. These cams swivel about their bearings when the draw pins of the die are forced downward, the draw pins resting on plate and spacer block placed on top of the cam housing. The swivelling of the cams on their bearings causes a vertical movement of the rollers and so controls the compression of the spring in operation. This compression is naturally less than if the spring was not provided with compensating members. The friction between the rollers and cams caused by the spring forces the cams to return to their original positions when pressure is released from the draw-ring. An adjustable nut placed on the lower end of the sleeve provides means of regulating the original pressure on the spring. The die cushion is manufactured by the Marquette Tool and Manufacturing Co. of Chicago, Ill.

Buyers Have the Say

AN ENCOURAGING improvement can be noticed on the machine tool market this last few weeks. Not that the improvement has been sensational, but a better tone exists. Prospects are showing more real interest and although the orders closed so far have been small, several real deals are developing.

Luckily for makers of machine tools, the improvement is coming their way. Manufacturers are enquiring more and more for new tools rather than second hand equipment, and this may be owing to the fact that they are at last realizing, what we have told for some time, viz, this is a buyers market. The purchaser to-day can get better bargains than for many years past. Competition is keen, and it is questionable if a similar period to that existing at present will ever return again.

In many cases dealers and manufacturers are selling below replacement cost to liquidate stocks. Now is the time to buy equipment, for if the prospective purchaser is reasonable in his demands and does not try to take an unfair advantage of the situation. he can secure a real bargain.

This applies not only to all lines of machine tools, but small tools and supplies as well. Drill prices are cut to the bone, and even the quotable market price is forgotten occasionally if a good sized order comes along. There is an old saying about making hay while the sun shines, and now is the time for the manufacturer to gather his hay in the form of good bargains in tool equipment.

* * * *

Now is the Time to Clean Up

THIS IS CLEAN up week. Get rid of all rubbish. Throw out anything that is not actually required. Clean up those dirty corners. These slogans and many others of similar character greet us from the pages of the daily press these days, for all cities are in the midst of their spring cleaning campaign. But how about manufacturing plants. Should they look at these slogans and say "Oh, that applies to ordinary residences"? To our mind it applies to every factory, large or small just as much as it does to any home.

Instead of cleaning up once a year however, there should be periodical clean ups. Not simply the sweeping of the floors, whitewashing of the factory, or the ordinary clean up duties, but a tool and equipment clean up.

Get rid of old files which are only taking up room, and perhaps the man's time who is trying to use them. Throw away old stubs of drills that have outlived their usefulness much as you may hate to part with them, for ten chances to one they are so short that when you use them the chips clog up the hole, and wasted time results.

These are only two of many other ways of cleaning shop. Some of your vises may be more bother to you than they are worth, the old brooms really don't clean the floor correctly any more, and some of the trucks you may be using are on their last legs. Machine tools are by no means exempt, for if several of the tools now in use could only speak, some owners would get a pretty red face.

We have in mind a lathe, that because it happened to be extremely well built to start with, is still doing service at the old stand, but at what a sacrifice. Only one man in the shop can run it, as he is the only worker who knows where the bed bends, and knows exactly how far to ease back the tool in order that a true (?) surface can be secured.

This editorial is not a plea to purchase material you do not actually require, but when you should buy, do not shut your eyes and say, "Oh, it will do for the present." Every time you fool yourself in this way you are losing money. Forget the initial expense, look further ahead, and you will soon discover that the cost of the new machine, the new drill, file, or vise, is soon wiped out by the added production secured.

Research is Essential

BECAUSE an industry has shown phenomenal growth is no reason why the leaders in that industry should rest on their oars and say contentedly "We have done well indeed." The automobile trade is a case in point. Here we have an industry which has jumped by leaps and bounds, and, while it is admitted that many improvements have occurred since its innovation, there is yet great room for improvement.

Take one example, valves. We know the material from which they are made is better than several years ago. but, engineers admit they have not secured an ideal metal yet. A valve to be successful must be able to work at a fairly high temperature, be non-corrosive, distortion proof, and wear resisting in quality. The stem must be able to take a high polish, yet resist wear, and with all these requirements are many others including ease of machining. A better valve material will be discovered eventually, but why not as soon as possible?

There is a great need of some research committee devoted to not only the automotive industry, but other lines. This body could be subdivided into several sections, the members being specialists in the group they represent. At present the United States have several research committees, including mechanical engineers, automotive engineers, etc., but all these are honorary positions, and do not make the same progress as a body of men working continuously would accomplish.

The only true solution is for the different industries to get together and support a central investigating committee, appointing both practical and theoretical men to the positions. One will balance up the other, and without either one, the judgment is likely to be very much one-sided. Pay these men good salaries, making it distinctly understood that reasonable progress must be shown, otherwise other members will be appointed. In fact, it would be a good idea to made changes occasionally for new blood brings new viewpoints, but the real valuable man should be kept on as the backbone of the committee. A move of this kind would have to be developed gradually, but one thing sure a start should be made as soon as possible.

Steel Prices Firm But Demand Only Seasonal

Practically All Lines in Market Report April Business Better Than March—Small Tools and Supplies Fairly Active—Machine Tools Show Better Tone—Pig Iron Demand Tapers Off Slightly

NO IMPORTANT CHANGES OCCUR DURING WEEK

THE Canadian iron and steel market is firm, but no advance of importance has occurred. Seasonal improvement is taking place, but no more than has been expected. April business showed a slight increase over March, and from present indications, May will gain over April.

Bars and small shapes are principally in demand, although even these lines cannot be termed features for the call is not strong enough.

Small tools and supplies are moving at a fairly good rate, and if the present strength continues, and it is expected that it will, May should show an increase over April. Competition is very keen, prices being cut to the bone in many cases.

Machine tools are steady but not brisk. The tone is better, prospects are showing more interest, and several good deals are under way. At present these look very rosy, but when they will break is another matter. This is a buyers' market, with the result that several good purchases have been closed, that is from the buyers' bargain viewpoint.

Montreal reports a good demand for building supplies and lines such as spikes, nails, bolts, and heavy hardware. Merchant bars are also active in that locality.

Non-ferrous and scrap metals are quiet in Toronto district. Montreal shows some price advances in scrap metals, but as the demand is weak, these prices mean little or nothing.

Miscellaneous lines such as waste, oils and steel pipe are all in fair demand, pipe being the most active of those mentioned. Bolts are rather strong in some quarters, one firm working overtime to supply the demand.

The motor industry is very lively, and textile trades are also busy. Business generally is improving gradually, and reports from various centres show that this improvement covers a wide field.

Finished steel prices in the United States are very firm. Shading has disappeared entirely, and some mills are even demanding advanced prices. On small tonnages they may get the premium price, but regular quotations apply to larger orders.

Pig production increased during April 5 per cent. over March. A few districts showed a loss, but the total production rate registered a gain. The coal strike was responsible for the lower rate in some localities.

The steel market still shows good signs of strength. Consumers in some cases are becoming anxious and importuning mills to accept their orders. The majority of steel ordered, however, seems to be going into stock. Based upon activities of the past three weeks, the rate is around 36,000,000 to 38,000,000 a year.

Connellsville coke offerings are very light, also the demand. Furnace coke is quoted at $6.25, and foundry coke $6.75. Connellsville coal has strengthened slightly during the past week, as Eastern buyers came into the market, and the price is now $3.

Toronto

May 10th.

CONDITIONS on all markets remain practically the same as last week. What activity exists is seasonal, and was expected. Competition is keen, especially in small tools and supplies, also machine tools.

Iron and Steel.—Business on this market shows fair activity only. Bars and small shapes are selling best of all lines, and prices are firmer than for some time past. Shading does not appear on the surface, but in a few cases, is being quietly followed out. This, however, is the exception rather than the rule, and therefore does not truly reflect the market tone, which is firm. A certain amount of local jealousy enters into the price shading, and the peculiar part about it is that the firms doing the cutting quote their regular customers the market quotations, but wherever the prospect of a new customer crops up, they offer special inducements, usually five or ten cents off the regular price.

Other steel lines are moving at a fair rate and, from present outlook, there is no reason why May business should not be ahead of April. Several dealers are still discussing the probability of an advance in bars and shapes, but so far it is talk only. Competition remains so keen that each one is afraid to make the move. Hoops are stronger, having moved up from 3.75c to 4.00c. This has been threatening for the past two weeks, because the spread was not as wide as it should have been. The new figure seems to be fairly well established, but no doubt if a really good order came along, dealers would forget the advance in their effort to bring home the order. Following are the local quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—The demand for pig iron is not quite so heavy this week, although it is still better than it was a month ago. The price remains the same, and foundries evidently feel they are well protected against the possibility of a drawn out strike, for they are not pleading for quick deliveries as they were a week or so ago. Prices are being given cautiously, however, for few know which way the cat is going to jump. Following is the local price:

Silicon 2.25% to 2.75%.....$29 15

Non-Ferrous Metals.—This still remains a draggy market with no price changes. The strange part is that while business closed has not improved the tone seems to be better. Dealers themselves feel that things are brighter, that people are more interested than formerly, and yet, when it comes to totalling up the weekly sales, no improvement can be recorded. Manufacturers are purchasing very cautiously, and seemingly only for immediate requirements. Following are existing prices:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	
Aluminum	26 00

Scrap Metals.—Here again we have a dull market. Prices are stationary, and whatever demand does exist is nothing to speak about. Quotations given below are firm, however, and we know of one or two cases where slightly more than the figures given had to be offered before material could be secured. If you know how to buy, the quotations given in this letter can be secured.

Copper, light .. per 100 lbs.	9 50
Copper, crucible	12 50
Copper, heavy	12 50
Copper wire	12 50
No. 1 composition	9 50
New brass cuttings	7 00
Red brass turnings	8 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	12 50
Boiler plate, per gross ton	8 50
Heavy melting steel	10 00
Axles (wrought iron)	9 00
Rails (scrap)	10 00
Malleable	10 00

Small Tools and Supplies.—May business looks to be shaping up nicely and if the present rate continues, will show an advance over last month. The demand is general, no line being featured. The automotive industry is helping this branch of the market as things are very busy in the border cities, Oshawa, and other cities where Canadian automobile factories are in operation.

Machine Tools.—The machine tool market is steady but not exceptionally brisk. Whatever business is closed is worked very hard for, but it is safe to

say that a much better tone exists. Prospects are showing greater interest, and dealers are doing more for customers today than in any other period in machine tool history. It is a buyers' market, and the slogan is "Satisfy the Customer." One large firm in the States has a special representative over here at present following up possible buyers. In one office we were in, a phone message was nearing completion, the important part of which ran like this: "That's too bad, we are very sorry to hear of the trouble, but do not worry, we shall send a man up at once, and make all necessary adjustment and repair." The said repair would cost a considerable sum, probably wipe out all the profit made on the sale, but to make themselves solid, they were willing to chase the matter to the very limit. We simply retell this incident to show how eager dealers are after business. Prices, such as they are, cannot be considered firm, because quiet bidding against each other is continually taking place.

Oils, Waste, etc.—No change has occurred during the week in oils, waste, or steel pipe. The latter is the strongest of all, deliveries being longer than for some time past. Following are present quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24

The demand for bolts is increasing in this locality, and one well known firm is working overtime to keep up with the demand.

Montreal

May 10

A SLIGHTLY better tone is evident in business circles. Nearly all jobbers report that business closed in April was larger than March. The demand for all kinds of building supplies is still good. Spikes, nails, bolts, and heavy hardware are moving nicely, and the increase in business which appears to be most significant is in marchant bars.

Machine tools and wood working machinery are occupying the attention of a greater number of prospects and all lines are showing a slight, but steady, improvement. It is difficult to pick out any special line that has been particularly active during the month, for the commodity that moves well this week will perhaps be sluggish next week. Thus when the figures covering a month are reviewed a better idea of the situation can be obtained. April figures from all quarters are better than those of March, showing that business is on the upgrade.

Iron and Steel.—Locally, business has shown a fair improvement during the week. It is difficult to discuss steel, without the subject of the coal strike being worked in. As far as local markets are concerned, the strike does not appear to have made the slightest difference. No quotations have been increased, and supplies appear to be ample to take care of business being offered. It is reported, however, that stocks in the warehouses of local jobbers are getting low and that it will be difficult to replenish these quickly. One must accept these statements reservedly, for such facts may have no bearing on the market, due to the unforeseen settlement of the strike, a slackening off in the demand, or for several other reasons. We are not entirely dependent on American fuel to operate our steel industries, and although prices are somewhat stiffer than they were a few weeks ago, this movement was in evidence in the United States before the strike became an established fact, being partly due to general improvement in conditions. The base price generally accepted is $2.75, but it is known that large consumers have secured steel as low as $2.65. Were a shortage really expected there would be very little price shading.

Take the base price at Pittsburg $1.50, and add to that the freight, duty, exchange, etc., and it is found that Pittsburg steel can be laid down in Montreal for about $2 53 base. Moreover, local jobbers are not organized, therefore are not adhering to any fixed base price.

Plates are not moving very well but sheets are fairly active. One jobber reports that they were all sold out of standard sizes and gauges before the recent shipment by water arrived. At this writing they are again sold out of standard sizes and gauges, and are awaiting the arrival of the second water shipment. Merchants bars are again in rather fair demand and a reasonably large tonnage is expected to be moved within the next few weeks No rail orders have come through up to time of writing, but it is confidently expected that when these orders do materialize, they will be for a large tonnage. Considerable orders for small lots of structural shapes have been coming through, this representing a very fair volume of business is general and comes from varied sources. No advance in quotations has been made locally, and following are local quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—No change in pig iron quotations have been made during the week. Prices are firm and sales are restricted to thirty days. The volume of business moving has eased off a little but there is still a fair amount of buying. No. 1 iron is being quoted at $31.80. Shortage of coke in some of the U. S. blast furnaces has had the tendency to curtail production and to make the price firm. The buying seems very general as not only have the small foundries covered their needs but some of the larger ones have come into the market to a limited extent.

Machine Tools and Supplies.—This market is very spotty. There is evidence that more firms are lining up as probable customers, a greater interest being taken in the market, but up to the present there has been little encouragement in the form of sales. Wood working tools have been in a little better demand during the past few weeks, but this has slackened up slightly, while iron working tools have improved a little leaving the general volume of business about the same. The supply business seems to have had a break in some quarters. Some dealers report that business is poor while others state it is improving. No price changes have come through during the week, but the increased activities in local and contract shops will no doubt create a slightly increased demand. April business closed in most cases exceeded those of March

Non-ferrous metals have had another inactive week. Sales have not quite been up to the average. Foreign markets are firm and business seems to be improving. Local quotations remain practically unchanged, and quotations are as follows:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 00
Lead	6 75
Spelter	7 50
Antimony	6 50
Aluminum	23 50

Scrap Metals.—The demand for scrap metals has been somewhat better during the past few weeks, and quotations have been advanced to a point where they are almost prohibitive. As these prices are beyond that which consumers can afford, it is difficult to make a list that would represent a figure that would permit business to be transacted. There has been an increasing demand for scrap in the United States, but so far as can be ascertained little scrap has found its way over there from local dealers. It appears to be a case of putting up the price as the demand appears. The following list is what dealers quote, but where a good offer appears they would no doubt accept a somewhat lower figure.

Copper, light, per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00

Medium brass	4 50
Yellow brass turnings	4 75
Light brass	3 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Pittsburg

May 10th.

PRODUCTION of pig iron in April was 5 per cent. greater than the average rate during March, and was approximately equal to the rate at the end of March, as during that month there had been a steady increase.

The Pittsburg district and the Mahoning valley went back during April, from the rate existing at the beginning of the month, but did a shade better than their average for March. The Shenango valley showed a moderate increase, and the Chicago district a large increase. The Wheeling district and Southern Ohio had losses.

Cases of restricted production were due to the coal strike, or rather to one part of the general coal strike, viz., the trouble in the Connellsville region, of non-union men who were induced to "join" the United Mine Workers by payment of $1 or $2 initiation fee, but who will receive no strike benefits. Production of the Connellsville region is about one-third the rate in March. As these strikes were not expected, consumers tributary to the Connellsville region were not well stocked, as were consumers normally using union coal, for the latter laid in large stocks prior to April 1, some beginning as early as last December.

There has been no material change in the strike situation during the past week. The regular union strike goes on and will hardly come to a head for many weeks yet. Some observers predicted in March that the strike would not be ended until five or six months had elapsed. The non-union strikers are in a different category, and are expected to end sooner but even here they are practically certain to last quite a while yet. Five weeks have already elapsed and the men show no signs of weakening. They are not getting out additional mines, however.

Iron and Steel.—The steel market presents an appearance of great strength, with some anxious consumers importuning mills to accept orders, while the mills are accepting orders cautiously, while a few of the independents have announced advanced asking prices. It would look, from the surface, as if a shortage of steel might develop in a month or two.

These surface indications, however, are not to be trusted, and probably would be quite misleading if followed. Looking deeper one sees a large production of steel with heavy shipments and consumers running along smoothly. Some consumers may wish to buy more steel, being alarmed about the future, but there is no case of any consumer restricting his operations because he has not enough steel. What has occurred in the past four months by way of greatly increased production and shipments would indicate that distributors and manufacturing consumers must have accumulated stocks of considerable magnitude, for there has been no evidence of actual consumption being equal to the production.

It will be of interest at this time, when a fairly steady rate of production is in prospect, to trace the ups and downs of production of steel ingots in the past two years. In the first nine months of 1920 the average rate was 42,000,000 tons a year. By the middle of July, 1921, the rate had dropped to about 10,000,000 tons. Then an increase began and a rate of about 25,000,000 tons was reached by November 1. At the end of the year the rate was much lower, probably under 17,000,000 tons. Then production increased rapidly, to 30,000,000 tons March 1, and 35,000,000 tons April 1, while the rate in the past two or three weeks has been between 36,000,000 and 38,000,000 tons. These figures are approximate, being based on estimates, but they are pretty close. Comparing industrial conditions from time to time, one cannot believe that actual consumption varied as greatly as did production. At some time buyers were accumulating stocks and at other times liquidating stocks. Even in 1920, when steel appeared very scarce, some buyers were carrying stocks. This is hard to believe, but is proved by the fact that in the past few months mills have had claims for detective steel, shipped during the first six months of 1920, the buyers only recently taking a look at it.

Whether the steel was defective or not, has nothing to do with the point at issue, viz., that buyers kept the steel instead of using it or even looking at it. In 1921, on the other hand, buyers were liquidating stocks of steel and there was also liquidation of goods made from steel. The natural conclusion from the figures cited is that a considerable part of the steel shipped in the past three months has gone into stock.

The change in the steel market is due to psychological rather than physical influences. Buyers are alarmed, rather than short of steel. Fear that there will be a shortage of steel owing to the coal strike does not seem reasonable, for the iron and steel industry is fairly well stocked, and if there were a general and serious shortage of coal, this would interfere with the consumption of steel. A similar lack of judgment has sometimes been exhibited in connection with labor supply, there being fears that with a labor shortage steel could not be made whereas labor shortage would affect the consumption of steel more than its production.

Finished steel prices are very firm, concessions from regular prices having entirely disappeared. Some mills are demanding advanced or premium prices, and are probably obtaining these prices on some small tonnages. Regular market prices are: Bars, shapes and plates, 1.50c; bands, hoops and hot rolled strips, 2.00c; standard steel pipe, 71 per cent. basing discount; blue annealed sheets, 2.40c; black sheets, 3.15c; galvanized sheets, 4.15c; automobile sheets, 4.50c; tin plate, $4.75; plain wire, 2.25c. Nails are held at $2.40 by the American Steel and Wire Company, and at $2.50 by independents, who advanced recently. The leading interest is of course picking and choosing the business it accepts.

Merchant furnaces in this general district are out of the market, as are consumers, there being only an occasional inquiry. On a forced purchase one would probably have to pay about $24, furnace, for either Bessemer, basic or foundry.

Connellsville coke offerings continue very light, and demand is likewise light. The market, what there is of it, is quotable at $6.25 for furnace and $6.75 for foundry. Connellsville coal, after weakening some ten days ago, has stiffened during the past few days, chiefly on account of the appearance of eastern buyers, and is bringing fully $3.00.

SEA SLEDS TO BE MADE BY CANADIAN VICKERS

The shipbuilding firm of Canadian Vickers, Montreal, have obtained the Canadian agency of the Sea Sled Co., and will manufacture and sell this product under license. The commercial demand for sea sleds, which are a new type of power boat, and which it is believed will revolutionize entirely the motor and power boat industry, is taxing the company's American plant to its full capacity. The taking over of the Canadian end of the business by the Vickers Company will mean that the large demand from Canada will be immediately taken care of by the Vickers Company's large and complete organization. The latter company will pay to the Sea Sled Co. royalties on all boats built and sold.

Initial construction work has already been started on several boats, the first of which is expected to be launched in a few weeks. Among those interested in the new venture are: C. R. Hosmer, Col. Herbert Molson, J. W. McConnell, W. A. Black and the Hon. W. J. Shaughnessy, etc. To consolidate the association, A. R. Gillham, the vice-president of Canadian Vickers, has been appointed to the board of directors of the Sea Sled Co., Limited. The latter company is purely Canadian, but owns the basic patent rights for Canada, United States and its dependencies, the company's present plant being at Mystic, Connecticut.

Mr. Ferguson, of the Toronto office of the Pratt & Whitney Co., and John Bertram and Sons, Dundas, is at present on a business trip in Northern Ontario.

Foreign Trade and the Standard of Living

FOREIGN trade is essential to the United States if American people are to maintain their present high standard of living, James S. Alexander, president of the National Bank of Commerce in New York, told delegates to the Ninth National Foreign Trade Convention this week. "We have established upon this continent an economic society that has given to the average laboring man a higher standard of living than his fellow laborer enjoys in almost any other part of the world," he said. "The existence of that standard constitutes one of the greatest achievements of American democracy. This standard, however, has been conditioned upon the maintenance of the productivity of the laborer and this productivity in turn has been conditioned upon the continued enlargement of the supply of highly productive land as fast as population grew.

"While there still undoubtedly exists a considerable amount of land which may be cultivated more profitably than land which is cultivated in some other parts of the world, yet we must recognize the fact that we have reached the point where upon the new land the operation of the law of diminishing returns in agriculture will cause a smaller and smaller yield of foodstuffs per unit of labor than has resulted in the immediate past. It is true that invention and improved methods of farming have tended to postpone to some extent the early working of the law of diminishing returns but the evidence of the last few years points clearly to the fact that we are now utilizing less fertile land at a greater per unit cost of production than was the case in former years.

"If we are to maintain our standard of living under a condition of diminishing returns in raw production we must offset such increased cost by devoting a larger proportion of effort to those lines of industry that yield increasing returns per unit, namely, to manufacturing. That we are doing this to some extent is evidenced by the census figure for manufacture. It should be borne in mind, however, that this process of offsetting diminishing returns in agriculture by increasing returns in manufacture involves an ever-expanding market for our manufactures and that such an expansion points unmistakably and inevitably to the extension of our foreign trade.

"From the most important point of view that a nation can take, therefore, namely, that of the standard of living of the masses of the people, we must have foreign trade to an ever-increasing extent."

Mr Alexander argued against the belief that domestic trade alone can assure the prosperity of the United States. He declared that domestic trade is in fact dependent on progress in the international field, since this gives an outlet for surplus production and for industries overexpanded by the war, and thus prevents price demoralization. Although America's foreign trade is only 10 or 15 per cent. of its total commerce, he pointed out that its importance can not be measured by this ratio, saying that many of the most important things in financial and business life hang upon percentages of less than 10 or 15 per cent. and the average reduction from normal business during the entire period of a depression may be under 15 per cent. A change in foreign trade representing only 5 per cent. of total commerce may mean a 20 to 40 per cent. loss to some of our important industries. In conclusion he said:

"The welfare of other nations is so closely interwoven with that of the United States that if the question of our foreign trade is to be interpreted with any degree of breadth whatever, it should be considered in the light of the trade of these other nations. There can be no final recovery of the domestic trade in any nation until the normal international trade relations which alone support the great international division of labor can be re-established.

"This conception of the real nature of both domestic and international trade in modern industrial society should prevent us from reverting to the foolishly selfish mercantile doctrine of the 18th century. We should strive to obtain all of the trade of the world that in a fair field with free competition we may gain through our own efficiency. I have no sympathy, however, with those who would wish America to grab more than her proportionate share of the world trade.

"While the first fruits of such a policy might seem to suggest that we were the gainers in an economic sense, it is impossible for us to maintain such trade unless we are fitted to hold it in an open field. Moreover, to the extent that we should attempt to obtain a disproportionate share and to hold it, to that extent would we prevent the most efficient working of the world machine and to that extent must our actions finally redound to our own injury as well as to that of other peoples.

"In the last analysis, therefore, I should rather view this question in its broadest aspect and answer the question as to why we should have international trade by recognizing why the world must have international trade."

The above is a summary of an address delivered by James T. Alexander, president of the National Bank of Commerce in New York, at the Ninth National Foreign Trade Convention, Philadelphia, on May 10.

Never use a guide stick to keep a belt on a pulley. Find the cause of the trouble and remedy it. See that the shafts are properly aligned, the joints of belt properly cut and laced square, pulleys true and correctly crowned.

INDUSTRY IN FORT WILLIAM

Plans have been completed for the construction of a new main yard office for the C. P. R. in Fort William, to replace the one destroyed by fire last February, and the erection of the structure will be commenced immediately.

In connection with the amount of power Port Arthur is expected to absorb, Manager M. M. Inglis, of Port Arthur Utilities commission, states that by next year the total should reach 20,000 horsepower. It is estimated that the paper mill now under construction at the pulp plant of the Provincial Pulp and Paper Co., north Port Arthur, will require 3,000 horsepower. The old Kaministiquia Pulp mill now owned and operated by the Wisconsin Rapids interests, is now using 3,000, and the extension to the Richardson grain elevator will take care of an additional 250 horse-power. The Parrish-Heimbecker elevator now under construction will want 250 horsepower, which will later be increased to 500.

Port Arthur building permits for 1922 to May 1, have reached $850,036 compared to $51,709 for the first four months of 1921.

The John East Construction Co., of Fort Frances, was awarded the contract for the construction of an eight roomed modern school building to be erected on Crawford avenue, west Fort William. The price was $71,183.16 including heating, plumbing and wiring.

The Dominion Engineering Works, of Montreal have been awarded the contract for the building of paper machines for the Provincial Paper mills, Port Arthur, at a price considerably over $125,000. The contract calls for the delivery in six months of one 146-inch paper machine, capable of turning out 500 feet of paper per minute.

Zinc mining is destined to undergo a revival in the Fort William district after almost a quarter of a century of quiescence, by the establishment immediately, at Ozone siding, a point ten miles east of Nipigon upon the C. P. R., of a refining plant primarily intended for the treating of ores upon the claims of the company erecting the plant, and also for the treatment of any other kind of ore that may be delivered to the mill. According to James Lawrence, who recently returned from a trip to Chicago and other points in the states, a company has been incorporated under the laws of the state of Illinois with head-quarters at Rock Island, known as the Ozone Zinc mining and Refining Association. It is capitalized at one and a half million. Mr. Lawrence says that operations will be started immediately, that it is expected that the mill will be producing and shipping inside three months. The property at Ozone is within half a mile of the Canadian Pacific railway, and a mile of a deep water harbor on lake Superior.

With a good quality of babbitt and the proper kind of ladle—one with a small-pointed spout—there is no necessity for a large hole when pouring.

SELECTED MARKET QUOTATIONS

News From the Industrial Field

A certain activity is developing among manufacturers of electrical equipment, due in some measure to the demand for radio equipment.

E. McNevin, of Fegles-Bellows Engineering Construction Co., of Port Arthur, Ont., is on a business trip to Toronto this week.

The furniture factory and planing mill of McCall and Co. at St. Williams, Ont., was destroyed by fire last week; the loss is estimated at $175,000.

Burlington, Ont. The Coldovoid Underwear Co. may soon commence operations in this locality. A site is under consideration, and further plans will soon develop.

T. McKechnie of Nelson, B. C., has been promoted to the position of superintendent engineer of the C. P. R. British Columbia Lakes and River Service with headquarters and office in Nelson, B. C.

Hillis and Sons, of Halifax, iron foundrymen, have taken tenders for the contract of erection of a two story foundry building of concrete construction adjoining their present foundry premises, on Robie Street, this city.

George Waller of Truro, is building a large brick furnace at Beaver Dam, Halifax county, in connection with the concentration plant of the gold mine there operated by E. Gladwin, of Truro, and Mr. Murphy, of Beaver Dam.

The contracting firm of Adkinson and Dill, Vancouver, B. C., have submitted a proposal to the city to construct and operate a central steam heating plant capable of supplying steam heat and power to large buildings in the city. The suggestion will be brought before the City Council.

General Forgings and Stampings Limited, Merritton, Ont., whose new forging plant has been in operation about one year, report that in addition to a seasonable activity in motor car parts, a more diversified general demand is developing, indicating a more progressive industrial growth.

A reflection of the activity in general building operations is seen in the better demand for pipe fittings. International Malleable Iron Co., Guelph, report improvement also in the export market for this line. This company is now employing 250 hands 5 days a week in their foundry and machine shop.

The Parker Motor Car Co., of Montreal have made delivery of their show and demonstration cars to most of their dealers. Operations are going on rapidly at the factory and it is expected that work on a production basis will be in full swing the middle of June. The company is opening up a show room in Phillips Square.

The contract for the masonry, brick and carpentry work for the main building of the civic hospital has been awarded to A. L. Garvock at a figure of $220,884. Tenders for the plumbing, heating, wiring and ventilating will be received up to May 25, for the power house up to May 30 and for the service building up to June 1.

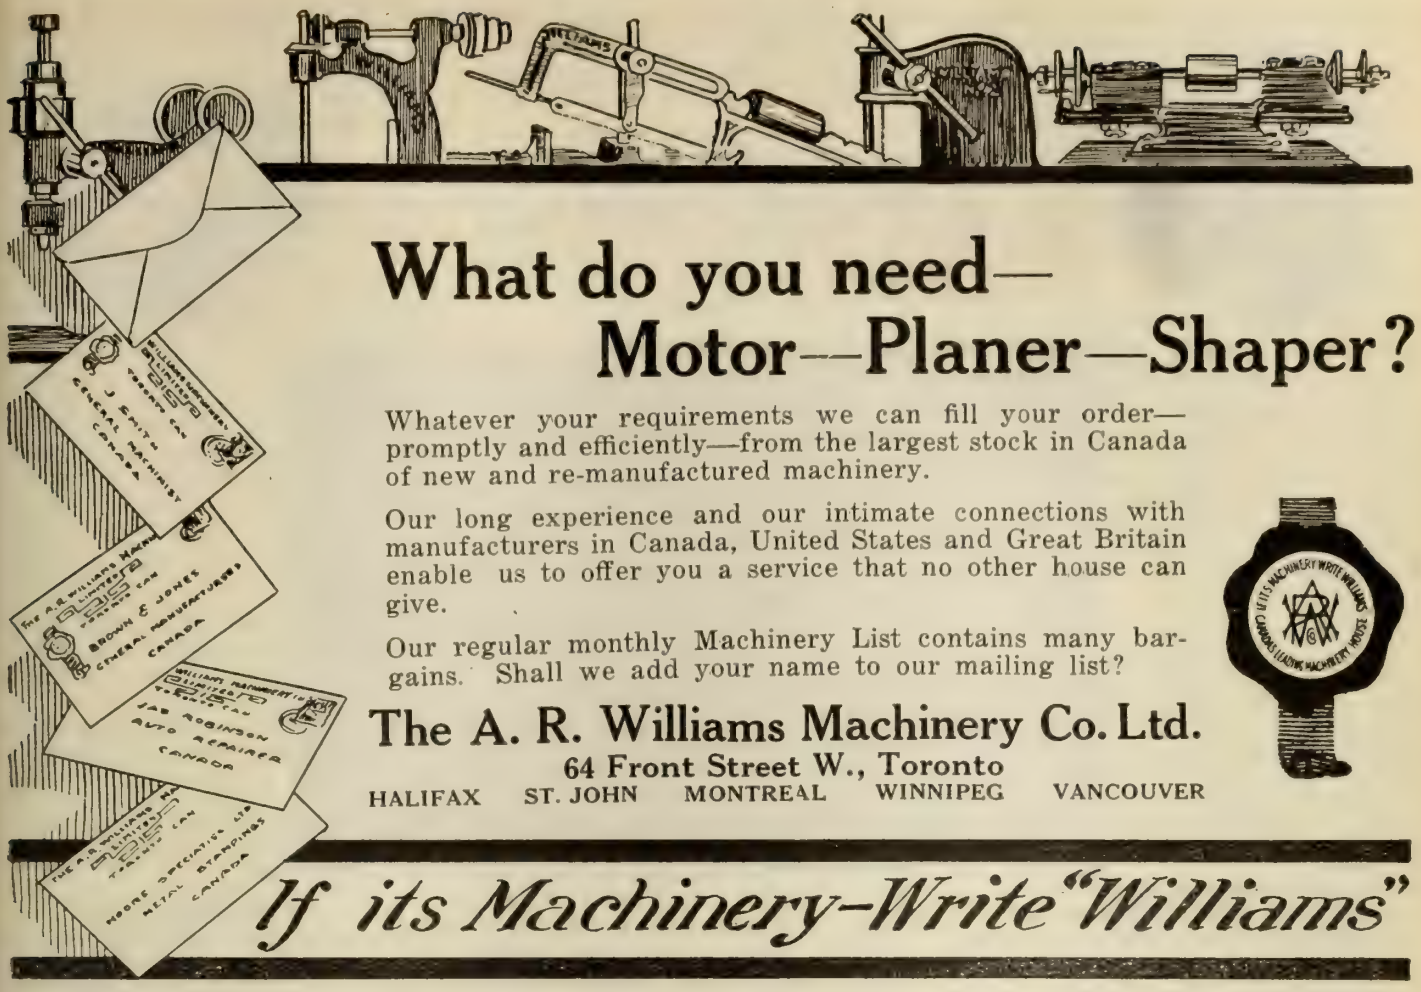
A better demand for taps, dies, gauges and various lines of small tools is reported from some quarters. The Greenfield Tap and Die Co., Galt, say that recent orders indicate a much more encouraging buying tendency and in larger lots. It is interesting that some of these are coming from the Maritime Provinces, when in March the outlook was anything but bright.

The copper output last year in British Columbia was about 39,037,000 pounds, which was nearly 6,000,000 pounds less than in 1920. The corresponding values were $4,879,624 for 1921 and $7,832,899 for 1920. The production of lead amounted to 41,402,288 pounds, an increase in volume of 2,071,070 pounds. Zinc produced was nearly 50,000,000, valued at about $2,000,000.

What is said to be the largest single shipment of freight for any individual automobile factory in Canada, consisting of 304 cars, valued at $350,000, left Oshawa for the Atlantic seaboard, to be re-shipped to foreign ports, including Constantinople, Egypt and New Zealand. The shipment, which represents a little less than two days output, was made by the General Motors, Ltd.

The gypsum areas at Iona, N. S. owned by the Iona Gypsum Co., have been sold at sheriff's sale at Baddeck under foreclosure of a mortgage of $50,000 held by the Montreal Trust Co. The claims were purchased by C. A. Mitchell, of New Glasgow, and associates in that town. The property was knocked down for $10,000. The Iona Company ceased working the property last December.

The Manley Co., York, Pa., manufacturers of labor-saving garage equipment, such as wrecking and underworker cranes, work benches, jacks, presses, etc., have made an arrangement with the L. and P. Manufacturing Co., Niagara Falls, Ont., for the production of their line in Canada. The Canadian Manley Co., will have their head office in Toronto. A. H. Fraser, formerly of Winnipeg will have charge.



A number of independent steel companies in the States are negotiating with a view of forming an amalgamation of their various interests. Among the firms mentioned are the Midvale Steel and Ordnance Co., the Republican Iron and Steel Co., Lackawanna Steel Co., Youngstown Sheet and Tube Co., Inland Steel Co., Prier Steel Co., and the Steel and Tube Co., of America. The aggregate capital of the Merger would be close to one billion dollars.

A made-in-Guelph exhibition is being held in the Armouries there this week. A very creditable display includes wood and metal working machinery lawn mowers, hardware line, pipe fittings and other products of the foundry, barn equipment and agricultural implements, stoves and furnaces, carpets, linens, women's wear, men's hats, incandescent lamps, pianos and organs, gasoline engines, metal products of various kinds and bacon and pork products.

The Public School Board has approved the recommendation of the building committee that the bulk tenders of the Gilmour Construction company for all trades in the erection of the proposed additions to Cambridge school for $27,297 and for the additions to Glashan school for $34,302.32 be accepted. Authority was given for the calling of tenders for the erection of an administration building at the corner of Gilmour and O'Connor streets, and for an addition to the Kent street school as soon as plans and specifications are ready.

Joseph T. Ryerson and Son, Chicago, announces that Paul H. Peterson, who has been associated with their foreign department for the past six years, will hereafter act as manager of exports. Mr. Peterson will be permanently located at their New York office and H. B. Krant, the previous manager of exports will hereafter act as technical manager of the machinery department. This change is made with the idea of giving the best possible service to the trade. All communications in connection with machinery and steel exports should be addressed to 30 Church St., New York, and the new cable address will now be "Ryson" New York. Several new developments and improvements in design of their lines have been completed recently.

These are the days when municipalities are releasing contracts to local foundries for manhole covers and catch basins. In Galt a considerable stretch of new sewer is being laid, and the contract for castings was let to the Galt Foundry Co., at $2.87 per hundred lbs. There is not a great variation in this figure among other Ontario towns and cities this year, whereas in the piping days of boom the price in some instances ran as high as $8. Of course, material and labor were then comparatively high. While there is not a great deal in it for foundries at present figures, such a contract very often enables them to run their heats with some regularity and thus take on other work which might have to wait or go elsewhere, sometimes to a neighboring town.

What do you need— Motor—Planer—Shaper?

Whatever your requirements we can fill your order—promptly and efficiently—from the largest stock in Canada of new and re-manufactured machinery.

Our long experience and our intimate connections with manufacturers in Canada, United States and Great Britain enable us to offer you a service that no other house can give.

Our regular monthly Machinery List contains many bargains. Shall we add your name to our mailing list?

Contracts were recently awarded for the erection of a four room addition to Ogden St. school in Fort William; also a new eight room school at Crawford Ave., the aggregate cost to be about $100,000.

The power plant and tipple of the Callic Mine at Drumheller, Alta., belonging to the Drumheller Land Co., was destroyed last week by fire, with a loss of $125,000.

The W. H. Yates Construction Co., of Hamilton, Ont., have secured the contract for the erection of the new Collegiate Institute and Vocational School at St. Catharines, Ont., the cost to be approximately $420,000.

Announcement has been made that the Shell Oil interests, refiners of oil and gas, with headquarters in Amsterdam, are negotiating for a site in Halifax with the intention of establishing a modern refining plant.

R. P. Ross and Co., Sudbury, Ont., have secured on behalf of the Standard Steel Construction Co., contracts for all the structural steel, for the new separate school, new parish hall and the Laberge Office Building, Sudbury, Ont.

The Hochelaga Cement Co., of Montreal are planning to erect a plant on their property in Montreal East, the capacity of which will be about 2,500 bbls. of cement per day. They will also provide for additional expansion.

The largest single shipment of shingles and copper to leave the port of Vancouver, B. C., went forward on the steamer Melville Dollar for New York a couple of weeks ago. It consisted of 2,500 tons of copper and about 20,000,000 shingles.

A new hydro-electric plant will be constructed this summer at Anyox, B. C. by the Granby Mining and Smelting Co. The cost will be about $500,000. The initial contract for the mammoth water storage dam has been given to Dredging and Construction, Ltd.

The Canadian Ramopo Iron Works, Niagara Falls, Ont., manufacturers of railway switches, crossings, etc., are completing an addition to their storage warehouse. They have just installed a 3½-ton Niles crane, purchased from the John Bertram Co., Dundas, Ont.

The Montreal Bolt and Forging Co., expect to start operations on Monday May 8. The company will produce all kinds of machine, carriage, and other rough finished bolts as well as lag screws, etc. By the end of May all departments will be in operation.

A record has been established at the plant of the Algoma Steel Corporation at Sault Ste Marie, in regard to fatal accidents. It is stated that the past winter has been the first in their history in which no fatality has occurred. A special safety campaign started in October, 1920.

The construction of another large hotel is being considered in Montreal. It is stated that the site selected is in the vicinity of the Windsor Hotel. Plans have been prepared and these call for a main building of ten storeys and two large wings. The value of the hotel will be about $5,000,000.

At a recent meeting of the Toronto Board of Education, the tenders were passed for the construction of the new technical school on Greenwood Ave. The total value of the structure will be $718,719, half of which will be paid by the Provincial Government. The school will be of the most modern type.

By a recent re-organization Wm. Le Bombard retires from the L. and P. Mfg. Co., Niagara Falls. The following new officers have been chosen: President A. W. Patterson: J. E. Kayser, sec.-treas.; Earl Lawson, vice pres. These officers are all actively identified with the operation of the company's foundry and machine plant.

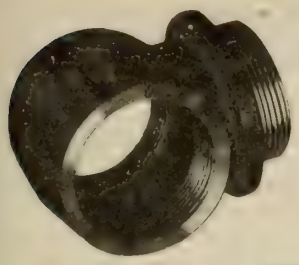
A report from London, Eng., states that the General Motors, Ltd., are establishing new works at Hendon, where they intend to assemble the Buick, Chevrolet, Oldsmobile and Oakland cars. These cars are manufactured from Canadian labor. The General Motors are also carrying stock of spares at Hendon valued at over $500,000.

A movement has been started in the United States, under the direction of Mr. Hoover, by the leading Engineering Societies of the country, to survey industrial conditions and ascertain "what steps have been taken to smooth out the business cycle." The present survey, which has just been inaugurated, represents an extension of the program of public service carried out by Mr. Hoover when he was president of the Engineering Federation, and which his successor, Dean Cooley, aided by a group of prominent engineers, educators and economists, is now carrying on.

Hermas Deslauriers of St. Mary, Montreal, is again making inquiries at Ottawa into the charge made in regard to the Aluminum Company of America using power from the Cedars Rapids. It is stated that this company has not paid any taxes on the power which it takes from this Canadian source and uses in the United States. The question was also asked if this company paid any license fee. If no contribution to the coffers of the Dominion of Canada has been made, it is rightly asked why this firm is exempted from the law in regard to the export of power.

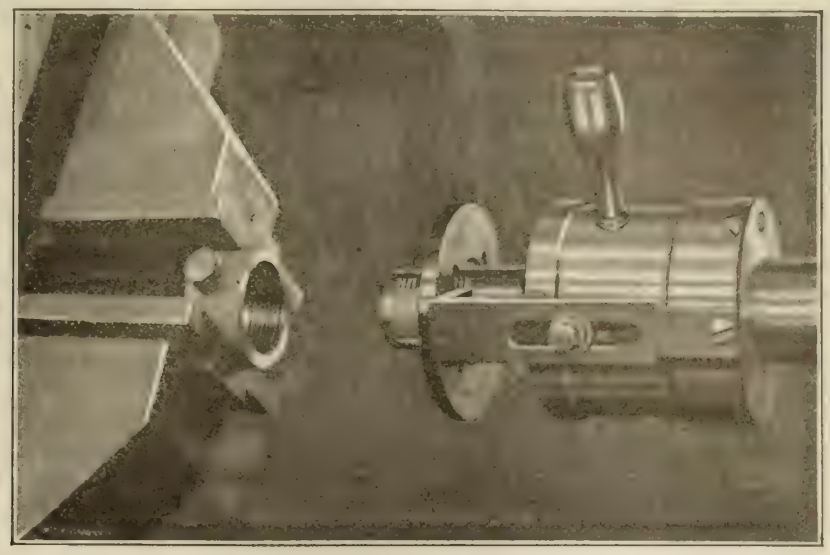
John D. Mantion, of Ottawa, inventor of match making machinery, claims that he has put to a final test a new match making machine that will eclipse all others of its kind. One year ago Mr. Mantion gave a demonstration in Nelson B. C. of his machine as originally devised, and states that it gave a result of 20,000 matches per minute. Since that time he claims that he has improved the machine 100 per cent. and that it now gives 40,000 matches per minute. He states also that the machine points the end of the match and that it is the only machine doing so. Six different grades of lumber in their green condition may be used with this system. It is further stated by Mr. Mantion that he has patented a devise for saw match blocks which will cut 130,000 blocks in nine hours with four men operating the machine. This machine cuts 100 matches out of a block.

Imminence of a building boom in the Capital is further indicated by building permits issued at the City Hall during the past month. For the month of April alone these permits numbered 162 and represented new construction to the value of $905,810, which contrasts very favorably with the corresponding month in 1921 when the figures were 82 permits, the total value of which reached only $593,925. For the first four months of the year permits issued number 272, representing $1,149,945; in 1921 the figures for this period were 149 permits, value $759,235. April 1922 both from the standpoint of permits issued and the estimated value of contemplated construction surpasses by a wide margin any building program that has been attempted in Ottawa for a number of years.



The permit for the new Collegiate Institute was the largest individual permit issued during last month. The estimated cost of the work is shown as $303,000. Next in magnitude comes the addition to the Ottawa University which is to cost $150,000.

NEW BRIDGE PLANT



Ground is being broken for the new plant of the London Bridge Works, London, Ont., which will be of modern steel fireproof construction throughout and equipped with the latest machinery for the production of steel structures of all kinds, chiefly bridges and buildings. This plant will be built on an improved factory site formerly owned by the Dominion Canners, located just off Dundas Road on the Grand Trunk Railway, consisting of about three acres, which will give them ample space for the time being. In conjunction with the regular business of fabricating steel, an extensive warehouse will be built and equipped for the distribution of iron and steel products of all kinds, including steel plates, structural shapes, iron and steel bars, black and galvanized sheets, etc. The plant and warehouse, when completed, will fill the long felt want in this part of the province and will render a much needed service to builders and contractors in the district.

The company is incorporated under the Ontario Companies' Act with $100,000, capital and the officers and directors are as follows:—president, T. J. Dillon, Welland, Ont., president of the Standard Steel Construction Co., vice-president, Geo. M. Reid, London, Ont. Directors Philip Pocock, London, Ont., E. S. Little, London, Ont., Col. I. Leonard, London, Ont., C. J. Madgett, Welland, Ont., F. C. Baker, Welland, Ont. C. J. Madgett, formerly assistant general manager of the Standard Steel Construction Co., of Welland, will take up permanent residence in London and be the general manager.

50 Per Cent. More Work With a Geometric Collapsing Tap Than With a Solid Tap

Anyone familiar with thread tapping knows what backing out a solid tap each time means. All the expense and annoyance of tapping screw threads with a solid tap have been overcome by the Geometric.

Special Taps for Special Jobs.

Standard Taps for Standard Jobs.

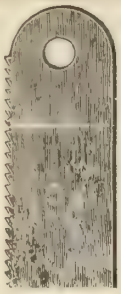
No doubt you and Geometric Screw Cutting Tools are not strangers. You may not realize, however, the number of styles that there are and the different classes of work that they are particularly adapted to.

Whatever the need in Screw Cutting, there is a Geometric to take care of it.

Adjustment to correct diameter each time a thread is tapped. Then chasers collapse automatically, leaving the thread clean cut and perfect.

The Chasers are readily reground, and when finally used up, are renewed at comparatively small cost, leaving the Tap as efficient as when new.

GEOMETRIC AUTOMATIC THREADING TOOLS



For cutting all classes of Screw Threads, internal or external, of any diameter and form.

The Geometric Tool Company

New Haven, Connecticut, U. S. A.

SIMONDS

Non-Breaking

Hard Edge
Hack Saw Blades

When you put a Simonds Hard Edge Blade in your Hack Saw Frame you are assured of the maximum of cutting service because these are the blades that cut fast, do not shell teeth and when properly used they are non-breaking.

They are scientifically heat-treated and smoothly finished.

"The Saw Makers"

Montreal, Que.

St. John, N.B. Vancouver, B.C.

Mr. S. S. Shoemaker, representing the Landis Tool Co., Waynesboro, Pa., is on special business in Canada. He is working in conjunction with the F. F. Barber Machinery Co., Toronto, by following up prospective purchasers of Landis equipment.

Brantford, Ont.—The Dominion Dress Goods Co. will erect a new three-story modern factory building, the present premises being found inadequate. As soon as this is completed, double the present staff will be employed. 150 are engaged at the present time.

Sarnia, Ont.—The ratepayers in Sarnia have voted a special assessment of $300,000 for the Dominion Alloy Steel Corporation, also a by-law for expenditure of $40,000 on improvements to present fire department. Officials of the Steel Corporation say that the first sod of the new factory will likely be turned sometime in June. The plant will occupy about 400 acres.

Advices from Point Edward, the distributing point of iron ore, state that a distinct revival in the ore industry can be looked forward to. Many boats are being chartered. Last year but 3,000,000 tons of ore were transported down the lakes, as compared with 56,000,000 the previous year. The record of two years ago is expected to be equaled this year.

Russian exports for January, amounted to $1,250,000, the goods being made up chiefly of oil products, flax, hemp and furs. The shipments went mostly to England, Latvia and Esthonia, a small part being sent to America. The imports for the same month amounted to 88,710 tons, valued at $11,400,000, this being exclusive of the food taken into the country by the several relief organizations. The imports show an increase of nearly six times as compared with January, 1921. The bulk of the imports came from Germany, with England next, then Latvia, the United States and Esthonia in the order named.

Dunnville, Ont.—Contracts for the new waterworks have now been awarded. Following are the firms who have secured work on this project. The Canadian Engineering & Contracting Co. of Hamilton will build the sedimentation basin, 25x60 feet, also the filter. The Arthur S. Leitch Co., Toronto, has the contract to supply the Roberts filter equipment. The Turbine Equipment Co. Toronto, will supply the pumping equipment, and when completed, the system will have a 40-horsepower service pump, pumping 750 gallons a minute.

ASBESTOS INDUSTRY

A protest and a warning against the suggested embargo on the export of raw asbestos from Canada was made at the annual meeting of the Asbestos Corporation of Canada by the president, W. G. Ross. Such suggestions, he declared, were ill-advised and ignorant, and he added that if such "foolish policies" were adopted it would sound the "death knell of the asbestos mining industry of the province of Quebec," for the reason that if such a policy were adopted the world supply of raw asbestos would come from Rhodesia, Russia and the United States itself, and Canada would mine only sufficient to supply such small proportion for her own needs that no mine could operate profitably. He added that at present approximately one per cent. of what is mined would supply the Canadian consumption. Nor could she sell, if she did manufacture, practically anything outside of her own territory.

LIGHT MACHINE TOOLS SHOW BETTER DEMAND

UPON information furnished by his head office in London, England, F. W. Field, H. M. trade commissioner at Toronto tells us that the heavier engineering trades continue to show some improvement in business especially with regard to export trade. The brighter spots of activity are in the locomotive industry, certain sections of the automobile trade, and in textile machinery. There are in addition other less prominent industries which appear to be doing well at the present time.

The Export Credits Scheme instituted by the British Government for the encouragement of export trade appears to be making great headway in the engineering trades and it is reported that a large number of firms are taking up under this scheme contracts which would otherwise prove unattractive.

A feature of the export trade has been the tendency of prices as between the leading manufacturing countries to converge to a common level, and it is generally anticipated that before very long the prospect of meeting competition from countries where the currency has depreciated will be much enhanced.

Light Machine Tools

Several things draw attention to the capacity of the United Kingdom for turning out light machine tools. This description does not refer so much to machine tools of accepted sizes and patterns designed on less heavy lines, but to machines for making small articles and articles requiring great accuracy of workmanship. The British light tool industry, therefore, falls naturally into two classes, the first dealing with tools used in model making and similar small work, and the second with tools used for making small gauges and similar work of high precision.

With regard to the former a great fillip has been given to trade by a recent exhibition in London dealing with model engineering. This exhibition was uncomfortably crowded from the time of opening until the doors finally closed and the number of orders taken was surprisingly high. There is an undoubted demand for small engineering appliances both for the home trade and for export and the prospect of an annual exhibition of this type is viewed with favour in many quarters.

of Metal Working Machines in Stock for Immediate Shipment. Prices Right.

SHAPERS

No.
653 1 McGregor-Gourlay 24" Shaper, complete.
1 Rae 16" Shaper.

MILLING MACHINES

671 1 Briggs, Type A, 22" traverse Manufacturing Miller.
2089, 1050, 1062, 3 Chicago Pedestal type, Hand Millers.
2088, 2088A, 618 3 Standard Pedestal Type Hand Millers.
1061 1 Garvin No. 2 Pedestal Type Hand Millers.
1072 1 Barber-Coleman No. 3 Tread Miller.
2075, 2086 11 Burke No. 1 Hand Millers, bench type, table 12 x 31½.
2087 1 Toledo Hand Miller, table 23" x 5".
876 1 Plain Dividing Head for No. 3 Miller.
1055, 1056 2 Pratt & Whitney 4½" x 12" Thread Miller with C/S.
642 1 Castellating Attachment for Miller.

BENCH LATHES

1029 1 Hardinge (Cataract) 7" x 32" Bench Lathe with head and tailstock, compound rest, plain rest.
734 1 Hardinge (Cataract) 7" x 32" Bench Lathe, with head and tailstock, compound rest, plain rest chasing attachment.

PRODUCTION LATHES

2005, 2012 8 Leblonde 17" x 8' Heavy Duty with C/S.
1098, 2004 6 Leblonde 17" x 6' Heavy Duty with C/S.
2013, 2016 3 Leblonde 17" x 6" Rapid Production with C/S.
2017 1 Reed 14" x 6" Extra Heavy Duty with C/S.

HACK SAWS

661 1 Peerless 6" x 6".
951 1 Perfect No. 3 6" x 6".
881 1 Millers' Falls 6" x 6".
1 Racine No. 1 Hack Saw.

TURRET LATHES

1036 1 Small Foster-Kimball C/S.
1031, 1040 4 No. 3 Foster, capacity 1 5/8 in. spindle C/S.
1041, 1043 3 No. 2 Foster, capacity 1 1/16 in. Spindle C/S.
2023, 2043 20 16" x 16" Bliss Heavy Duty.
2044, 2054 10 No. 2 Foster with round turret, capacity 1 1/16 in. spindle, C/S.
2055, 2058 3 No. 3 Foster with round turret, back geared capacity, 1⅝ in. spindle, C/S.
2061, 2065 4 No. 3 Foster with hexagon, turret, back geared, capacity 1⅝ in. spindle C/S.
2065 1 J. & L. 15" Turret, round turret, 1¼" hollow spindle.
2067 1 16" x 6' McGregor-Gourlay Turret Lathe.
2068 1 18" x 6' McGregor-Gourlay Turret Lathe.
2069 1 20" x No. 4 Bullard with hexagon turret.
2070, 2070a 2 16" Warner & Swasey Geared Head.
2073 1 17" x 6" Davis Lathe with round turret.
819 1 Oliver 18" Turret with C/S.
818 1 B. & O. 16" Turret with C/S.
815, 816 3 Davis 24" Turret Lathes with power cross feed.
1 Warner-Swasey Turret Lathe No. 6.

GRINDERS

590 1 Bench Type Double End, two stop cone pulley on spindle, no C/S.
1079 1 Wells Toolroom Grinder.
1067 1 Bench Type Double End, single pulley on spindle no C/S.
1069 1 Gardner No. 24 Grinder.
1070 1 Double End Emery Grinder on pedestal, two step cone pulley on spindle, 1" dia. spindle, C/S.
2109, 2110, 2 Perfect No. 6 pedestal Grinders.
2117 1 Sellers 5/16 x 3" Drill Grinder.

GRINDERS—(Cont'd)

898 1 Lafayette Universal Motor Driven Tool Grinder for lathe work.
1064 1 Symington Plain Grinder C/S.

GAP LATHES

656 1 C.M.C. 20" x 38" x 12' D.B.G., Q.C.G. face plate chuck C/S.

DRILLS

1 Reed Four Spindle Drill Press.
1048 1 Barnes 15" Sensitive.
1065 1 Perfect 14" Sensitive.
1066 1 Mechanic's 24" B. G. Drill Press.
1085 1 Perfect 15" Sensitive.
1088 1 Langelier 10" Bench Type with C/S.
1096 1 Ford Smith 22" Back Geared Drill Press.
954 1 Edlund 15" High Speed Ball Bearing Drill Press.
839 1 Fosdick No. 2½ Radial Drill.
675 2 Woodward 4 Spindle Drill Presses.
1 Rockwell 20" B.G. Drill Press.

SCREW MACHINES

1057, 1058, 1059, 3 Acme No. 55 4 Spindle Automatics.
1093, 1094 2 Garvin No. 1 Wire Feed C/S.
2071, 2072, 2 Warner & Swasey No. 6 with geared head, automatic chuck C/S.
1018 1 Warner-Swasey No. 1 Screw Machine.

ENGINE LATHES

1047 1 Cincinnati 16" x 8' D.B.G. screw feed, chuck, 2 face plated C/S.
1073 1 L'Blonde 17" x 6" S.B.G., Q.C.G. rapid production rod feed, chuck, face plate, C/S.
1038 1 13" x 5" Lathe Chuck face plate and C/S not screw cutting.
1078 1 Lodge & Shipley 14" x 6" S.B.G. Q.C.G. chuck, face plates, C/S.
1081 1 Leblonde 16" x 6' S.B.G. Q.C.G. chuck, face plates, Screw Feed, C/S.
1082 1 Hamilton 16" x 8' S.B.G. Q.C.G. screw feed chuck, face plates, C/S.
2018 1 Stevens 16" x 6' Engine Lathe screw cutting C/S.
2019 1 McGregor-Gourlay 16" x 7" Engine Lathe, screw cutting C/S.
2020 1 Stevens 16 x 8 Engine Lathe, screw cutting C/S.
2021 1 Stevens 18 x 8 Engine Lathe, screw cutting C/S.
2022 1 Lodge & Davis 18" x 8' Screw cuttings with C/S.
812 1 Putnam 36 x 18" S.B.G. Screw cutting, face plates C/S.
809 1 McGregor Gourlay 18" x 12" S.B.G. face plate C/S.
810 1 McKechnie-Bertram 20" x 10'. S.B.G., face plates C/S.
666 1 Rae 18" x 8" D.B.G. Q.C.G. face plate C/S.
1 Cincinnati 18 x 8 D.B.G. screw feed, Q.C.G. chuck, face plate, C/S.
639, 643, 646, 3 Speed Lathes.

BUFFING MACHINES

051-3, 3 Perfect 36" Pedestal Type 1¼ Spindle.
627 1 24" Perfect 36" Pedestal Type 1" Spindle.

TAPPING MACHINES

1063 1 Ricker Schaufer ⅜ Friction feed.
733 1 Burke Bench Type, horizontal ¼" capacity.
602 1 Burke Bench Type horizontal ¾" capacity.

PRESSES, PUNCHES & SHEARS

1035 1 Brown-Boggs No. 90 Kick Press.
944 1 Greenard No. 3½ Arbor Press.
742 1 Niagara No. 3 Arbor Press, pedestal type.
741 1 Niagara No. 3½ Arbor Press, pedestal type.
822 1 Stiles No. 172 Punch Press.
1020 1 Bench Type Punch.
1021 1 Bench Type Shear.
2108 1 Toledo No. 57½ Back Geared Power Press, 4 tee rods, 12" stroke, 140 tons cap, 6" Crank shaft, 24½" between uprights weighs approximately 35,000 lbs. Also a number of Bliss Inclinable Presses.

BLOWERS

A number of Buffalo, Sheldon, Soot Blowers of varying sizes and capacities.

PUMPS, ACCUMULATORS

831 1 Vertical 2 plunger, hydraulic 2½" dia x 6" stroke 1¼ inlet and d. charge.
813 1 Northey Duplex, 6" x 4" x 7".
780 1 Goldie McCulloch, 2" suction 1½" discharge.
799 1 Smart-Turner 4½" x 2¾" x 6".
2090 1 West Tire, No. 3, 2 cylinder plunger pump.
2091 1 Gould Triplex Plunger Pump.
2092 1 Perrin Triplex Plunger Pump
2093 1 Small Size Two Plunger Pump.
2119 1 Hydraulic Accumulator, 6 x 8 ram, capacity 10 Imperial Gallons, 1500 lbs.
2137 A number of lubricating pumps for use on Lathes, etc.

MOTORS AND ELECTRICAL EQUIPMENT

1031 1 Lincoln 20 H.P. 3 phase, 60 cycle, 220 volts. 1200 r.p.m. with base and pulley.
660 1 To. and Ham. 12 H.P. 3 phase, 25 cycle, 220 volts 1500 r.p.m. with base and pulley no starter.
634 1 Can. Allis-Chalmers 5 H.P. 3 phase, 60 cy. 550 volts 1200 r.p.m. with base and pulley.
1090 1 Chapman Walker 20 H.P. 3 ph. 25 cy. 550 volts with base and pulley.
2096 1 Robins & Myers ½ H.P. 1 ph. 25 cy. 110 volts.
2097 1 Westinghouse 50 H.P. 3 phase, 25 cy. 550 volts with base and pulley.
2096 1 Chapman Walker 40 H.P. 3 ph. 25 cy. 550 volts with base and pulley. 750 r. p. m.
1 Westinghouse 35 h.p. motor, 3 ph. 25 cy., 550 volts, with base and pulley.

MISCELLANEOUS

2099, 2102, 3 Strong-Carlisle-Hammond Continuous Annealing Furnaces, 22" long x 3" x 2½" opening.
2103 3 Strong, Carlisle-Hammond Furnaces
2106 forheating drop forge work.
2127 1 Brown Pyrometer 2000 Fahr.
2153 2 Southwark Hydraulic Physical Test-
2154 ing Presses, 2000 lbs. per sq. in. pressure, 2 column type fitted with intensifier ram, revolving table guard and suitable drain basin, mounted on pedestal and arranged for single lever control.
2155 Metalwood Hydraulic Testing Press similar to above.
1032 1 Jardine No. 50 Power Hammer.
1019 2 Sand Riddles.
946 1 Bellevue Oil Furnace.
888 1 Gas Furnace, 12" x 15" x 8" two burners, size of door opening 1"x8".
841 1 One-ton Portable Crane.
840 1 Two-ton Portable Crane.
689 1 Gas Furnace 18 x 11½ x 8" 2 burners, door opening 10 x 8.
2113 2 Bertram Stenciling Machines
2114 Steel.
2115 1 Holden Morgan Stenciling Machine.
2116 1 Burring Machine.
2118 1 Four pt. tapalog complete (Wilson-Maulin.)
2121 3 Brantford Counter Scales.
2123, 2124, 2125, 2 LeVilbiss No. 13 S.M. 152 Internal Varnishing machines.
Quantity of Wood Split, Steel Split Pulleys, Hangers, Belting, various sizes.
1 Blacksmith Forge.
1 small Anvil.
1 Barrett 15 ton jack.
1 Garvin No. 1 Slotter.

SITUATIONS WANTED

MECHANICAL DRAFTSMAN AND DEsigner desires position, preferably firm where advancement and responsibility is given. Competent chief draftsman with machine shop experience, well educated. Box 810, Canadian Machinery, Toronto. (C.18M.)

MANUFACTURERS' AGENT OPEN TO TAKE on one or two more lines. I call on the Wholesale Jobbers, Wholesale Accessory houses and the large manufacturers. Apply Box 809 Canadian Machinery. (C.15.M.)

MECHANICAL ENGINEER IS OPEN TO consider partnership or interest with manufacturer with a view to producing new high grade lines of engineering equipment. Must have good reputation and manufacturing facilities. Box 808, Canadian Machinery. (C.16M.)

SALESMAN, 6 YEARS' MACHINE TOOL EXperience, 10 years general engineering with A1 practical and theoretical knowledge of mechanics, open to represent manufacturer in Toronto and district. Box 805L, Canadian Machinery.

SITUATION WANTED AS SUPERINTENDENT or general foreman of machine shop, twenty years' experience. At present employed; best of references. Box 861T. Canadian Machinery. (c23m)

PRACTICAL FOUNDRYMAN, 25 YEARS ON light, medium and heavy work, green and dry sand. Bench, floor and machine molding, melt by analysis, and thoroughly competent on cupola practice. Good reference. Box 804. Canadian Machinery. (C11M.)

FOR SALE

ONE J. & J. TAYLOR SAFE, INSIDE DIMENsions 15 inches deep, 2 feet 6 inches wide, three feet 11½ inches high and fitted with a ouilt in compartment. Price $250.00.

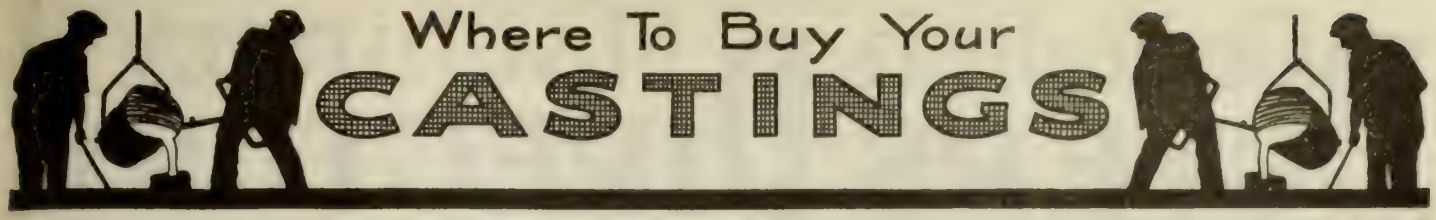
Machinery Wanted

Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

Put it There!

No, we're not shaking hands, but we would like to offer advice.

These columns have sold hundreds of dollars worth of equipment. A large number of men have been paid many times over by using these columns.



The easiest, quickest and cheapest way to dispose of, or buy new and used equipment.

Two cents per word. Minimum for one insertion $1.00. Box numbers can be had for 10 cents extra. Replies are forwarded immediately, and without additional cost.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

STYLE HEALD Nº55

REGRINDING HEADLIGHTS

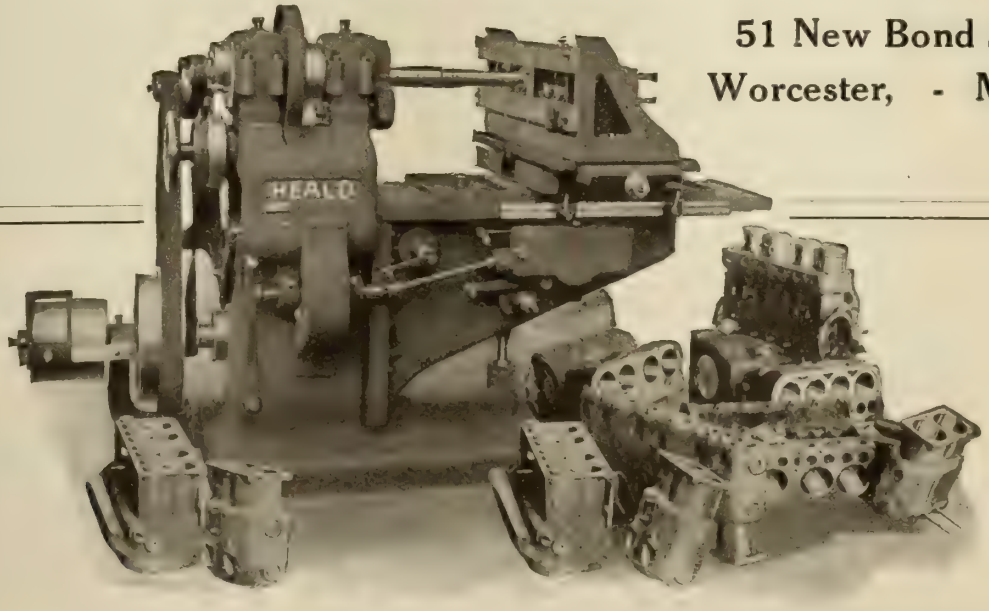
STYLE HEALD Nº65

For Centralized Repair Shops

If you are connected with automobile repair work in any manner such as a small machine shop, welding concern or even a regular garage, you are passing up an excellent opportunity if you do not look into the regrinding of automobile cylinders. Especially is this true if you are in the center of a large number of registered cars, not necessarily in the city but a strategic point in a medium sized town.

It is a new proposition to both repairmen and motor owners but its results are fast becoming known to both and the latter are, in a large percentage of cases, insisting on reground cylinders when overhauling to enable them to get a motor as good as new.

The commission usually allowed to garages is sufficient to make it a worth while proposition for them, especially when they are not in a position to put in the necessary equipment, and by obtaining work from all of these in your working center you will get unusually handsome returns on the investment. Once established you will create a market that now does not exist for there are many owners who do not know of the value of a reground block and still more who do know but neglect having it done owing to the inconvenience of sending the block away.



The Heald Style No. 55 was built especially for this class of work, simple, reasonably priced and with a range that will take care of any block that you may have whether it is from a pleasure car, truck, tractor, motorcycle or marine engine. Heald machines are used exclusively by every motor manufacturer that grinds his bores and motor owners who fully appreciate a reground job will insist on having it done on a Heald machine.

We would be glad to talk over the possibilities personally with you, giving you our frank opinion and furnish you with sufficient information to enable you to decide for yourself whether you can make a success of it or not.

Get in touch with us direct or through our branches or agents.

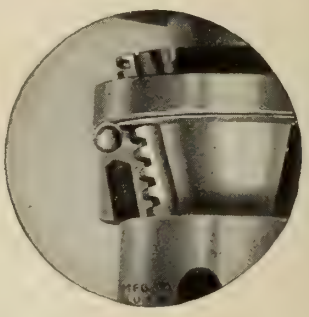
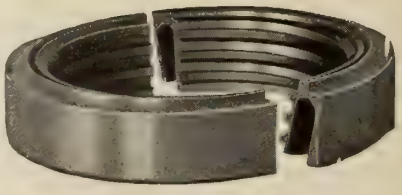
Worcester, - Mass.

Jacobs Super Chuck



Patented 1909-1915. Other patents pending

A Look Inside



Here are the several parts—carefully designed, exactly fitted, perfectly made—that guarantee the Jacobs Super Chuck to hold a drill tight, to hold it right, and to keep on doing its work indefinitely.

FIRST THE BODY—scientifically casehardened; size limits within .0005", arbor hole ground on a special fixture with six gauges to position it accurately in relation to the hole for the jaw.

THE SLOT FOR THE NUT, correctly located in relation to the jaw holes by means of micrometer gauges, insures a properly fitting thread on the nut and jaws.

NO WEAR ON KEY HOLES because of the deeply casehardened body, result—a well-fitting Gear on Sleeve and Key.

THE JAW, OF TOOL STEEL, has glass hard gripping surface; threads are tough, and all surfaces are ground on centers to within **a quarter of a thousandth** of an inch.

THE NUT, of special analysis steel, is ground after heat-treatment, in correct alignment with thread, tolerance .0005".

THE BALL RACE comes within limits of .0001"; finest grade balls are used. An important point is the pitch of thread on nut—angle is 90 degrees to center line of jaw, so part cannot run over thread of latter.

The Jacobs Super Chuck centers a drill, **accurately,** and will continue to do so after years of use. It saves its cost time and again by preventing drill breakage. Its correct balance preserves bearings of your drilling machine—order a Super Chuck from your dealer.

ANNOUNCEMENT

GROUND HOBS

NOW

MADE IN CANADA

IT IS no longer necessary to send outside Canada for Ground Hobs—or Hobs of any kind. A large and thoroughly equipped plant has been established by the **Canada Illinois Tools Limited,** at 163-187 Dufferin Street, Toronto, and is ready to take care of all Canadian orders. In this plant Ground Hobs are designed for your requirements and finished complete to your specifications. Made-in-Canada Hobs result in a saving of **time** and **expense** to Canadian buyers.

Engineering Service: Canada Illinois Tools are backed by competent technical service. When a Canadian Manufacturer is confronted with a problem affecting hobs or cutters he is advised to consult our service staff. If necessary we send an engineer right to shop with instructions to stay with the job until the problem is solved.

Have You Seen These Tools?

DRILL BLOCKS AND CLAMPS No. 278

A recent addition to Starrett sets of drill blocks. These blocks No. 278 are especially made to meet the demand for work requiring V blocks of the highest accuracy. Made of tool steel, with the V's ground central, parallel and square with the ends and sides, and hardened. Set consists of two drill blocks and two clamps. Blocks are 1¼ inches square by 1⅝ inches long. Clamping capacity, 1 inch diameter. Especially recommended for accurate work in connection with drill presses, laying out work, prick punching, milling, grinding, etc. Fully described and illustrated in the new Starrett Catalog No. 223 on page 214. Copy of this catalog sent on request. Write for it.

Every man interested in fine tools should have a copy of the Supplement to the Starrett Catalog. Send for this Supplement showing the latest additions to the Starrett line.

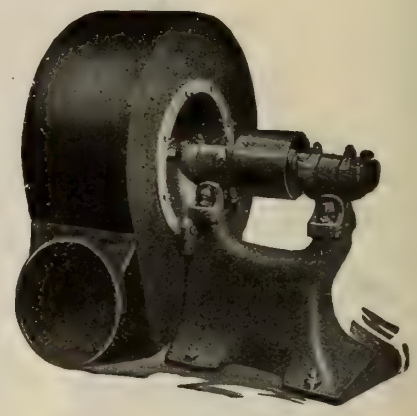
Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.



Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

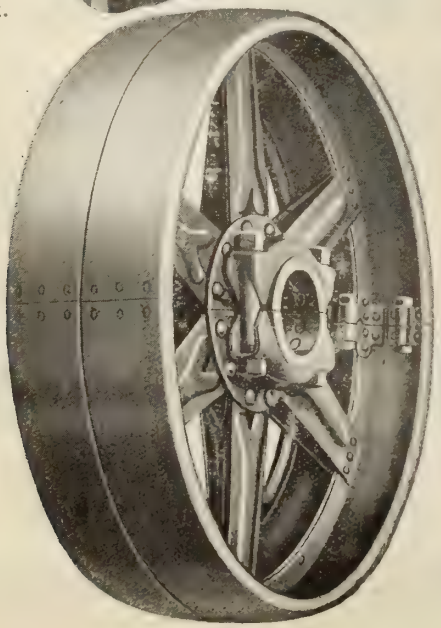
AMERICAN STEEL SPLIT PULLEYS

Let your engineers and ours work together



"UNUSUAL" problems in transmission call for unusual pulley service. We are prepared to render that service. Never are we so eager to "sell" as we are to make certain that the "American" Pulley will actually solve a given problem. May we also say that our many years of specialization often enable us to recognize a problem met by us before in what seems to others a new and "unusual" condition.

Service, however, is only one chapter in the story of "American" Pulley success. A book entitled "Getting Maximum Pulley Efficiency" gives the complete account. That book will help you to a greater saving in transmission of power, as it has many others. A copy will be mailed at once, on request.

The American Pulley Co.
Manufacturers of Steel Split Transmission Pulleys, Steel Sash Pulleys and Pressed Steel Shapes
Philadelphia, Pa.

For complete list of distributors see MacRae's Blue Book.

It is just as unreasonable to attempt a filing job with a file that has begun to get dull as it would be to run a machine without oil.

Full service from a file is possible only when the teeth cut keenly.

Discard a file as soon as it ceases to do this, and buy a new one.

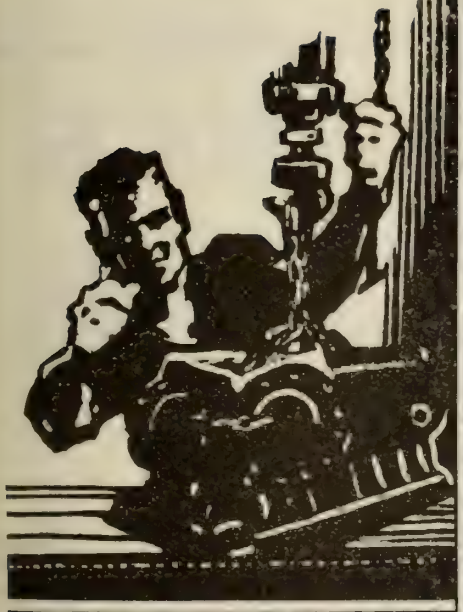
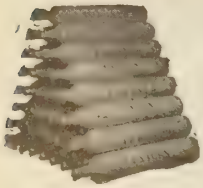
Kicks from his customers stopped when cleaning methods improved



A MANUFACTURER of automobile bumpers met with an increasing number of complaints from motor car owners that the nickel-plating on his bumpers turned rusty soon after purchase. Goods were returned for credit and replacement through trade channels until finally it was found that 21% of the entire output of nickel-plated bumpers was being returned as undesirable and defective.

Naturally this condition seriously affected the favorable reputation the manufacturer had built up through recent years on other auto accessories. Steps were taken to improve matters. Every detail of manufacture was scrutinized. Plating methods were checked and counter-checked. At last the trouble was located. The steel bumpers were not properly cleaned before plating.

In order to insure a chemically clean surface and to neutralize any traces of acid that might remain in the pores of the metal from the pickling operation, they adopted Oakite Platers' Cleaner. The bumpers were then nickel-plated perfectly. Within three months complaints and replacements were practically ended. Labor costs dropped 32% because the work was put through faster and better.



You, too, may be facing complaints about your product that could be traced to wrong methods in the cleaning room. Rejects and replacements often are due to, yet fail to be charged against, improper cleaning.

It incurs no obligation to have a friendly talk with one of our experienced Service Men. Find out what he can do to help you. Out of his broad experience and ability you are sure to get some helpful ideas that will be worth while. Won't you write now?

Battery of Bliss Automatic Gang Presses in production. Five operations each stroke.

BLISS AUTOMATIC GANG PRESSES

Bliss Automatic Gang Presses in some cases do five operations at each stroke of the press and without handling. This means two things, they secure you economy in production and eliminate danger to the operator. In addition you produce a finished article and do not accumulate quantities from each operation; a saving in floor space.

If you have not looked into this type of press, why not now? It costs nothing to do so and may mean a considerable saving to you.

We build special gang presses for individual requirements.

BROWN & SHARPE
UNIVERSAL
MILLING MACHINES

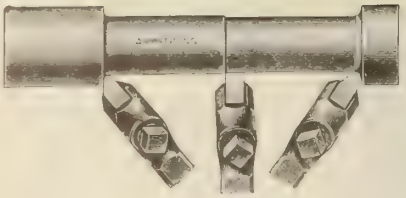
The heavy Universal—an adaptable machine

When a new milling machine is added to the shop equipment there is usually some definite job in view for it. It may be a lot of big, heavy castings, followed by another lot of the same kind. Or between jobs there may be a large fixture to mill.

Extremely accurate on large fixtures

As for fixtures—your tool makers may have had difficulties with an occasional big fixture—heavy, bulky—demanding accurate work to close limits. The manner in which the larger Brown & Sharpe Universal Milling Machines handle such tasks reveals their essential strength and precision. They are accurate, handy, thoroughly capable machines.

Always available for production work



If, when the fixture is finished, another production job is scheduled—there's the machine—put it to work. You'll find it has plenty of strength and stamina for all the work you can give it.

In our complete line is the machine for your work

Your problem may be quite different from the one outlined here. Whatever your problems are, send for our General Catalog listing our entire line, including six styles of milling machines covering a broad range of sizes. Become acquainted with the details and specifications of these machines. Ask for Catalog No. 137.

Brown & Sharpe Mfg. Co., Providence, R.I., U.S.A.

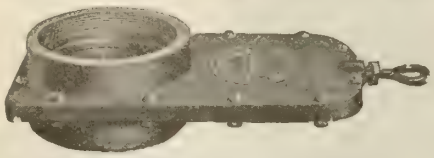
One Armstrong Tool Holder Equals A Dozen Forged Tools



It is apparent that it is the height of wasteful inefficiency to tie up capital in solid high speed Lathe and Shaper tools when less than one-tenth the amount of steel, if used in Armstrong Tool Holders, will do the work and save time and grinding as well.

One Armstrong Tool Holder with a few cutters, which can be quickly and cheaply made from the bar by any machinist, will do any job on the lathe or shaper; roughing, facing, finishing, corner and fillet work. It makes one pound of high speed tool steel equal to 10 pounds in forged tools.

ELIMINATE VALVE INEFFICIENCY

NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting. Threaded or Flanged connections.

Carlisle, Penna.
We are using your Blast Gate as an outlet valve on a starch tank. This tank contains a very heavy grade of starch—just liquid enough to flow. This heavy substance clogs the ordinary valve but your blast gate has, to date, given perfect satisfaction.
C. H. Masland & Sons, Inc

Hundreds of former valve users have found the remedy by installing Rockwell New Air-Tight Blast Gates.

This wonderful control device has proved an ideal substitute for expensive, heavy, cumbersome and slow-acting gate and globe valves when used for:

Air and Gases of Various kinds

Blast furnace coal and lime dust
Counteracting back pressures
Distillation processes
Pulverized coal
Chemicals handled through pipes
Gas engine exhaust lines
Soot chutes
Starch

Present industrial conditions make it urgent that you investigate the economy and efficiency of this New Air-Tight Blast Gate. Ask our Canadian distributor for Circular 210-T.

Opens Up New Business Possibilities

HEALD
CYLINDER
GRINDER

There's Big Business in Regrinding Cylinders

AT NO time in the history of the Automobile Repairing Trade has the value or necessity of having their cylinders reground been better appreciated by motor owners than the present time. Analysis shows that this is a field with unusual possibilities into which a great many small machine shops, welding concerns or garages can readily go with only a small investment.

The Heald Machine Company was among the first to appreciate the extent of this new field and brought out the

HEALD CYLINDER GRINDER

A new machine especially adapted for regrinding cylinders. The HEALD is now chosen by regrinding shops for its economy in producing the highest grade of work. Simplicity, accuracy and quick set-ups are factors that make its popularity.

You are passing up an excellent opportunity if you neglect to properly appreciate the possibilities of this field, especially if you are located in a section where a large number of cars are registered, either in the city or a strategic point of a medium sized town.

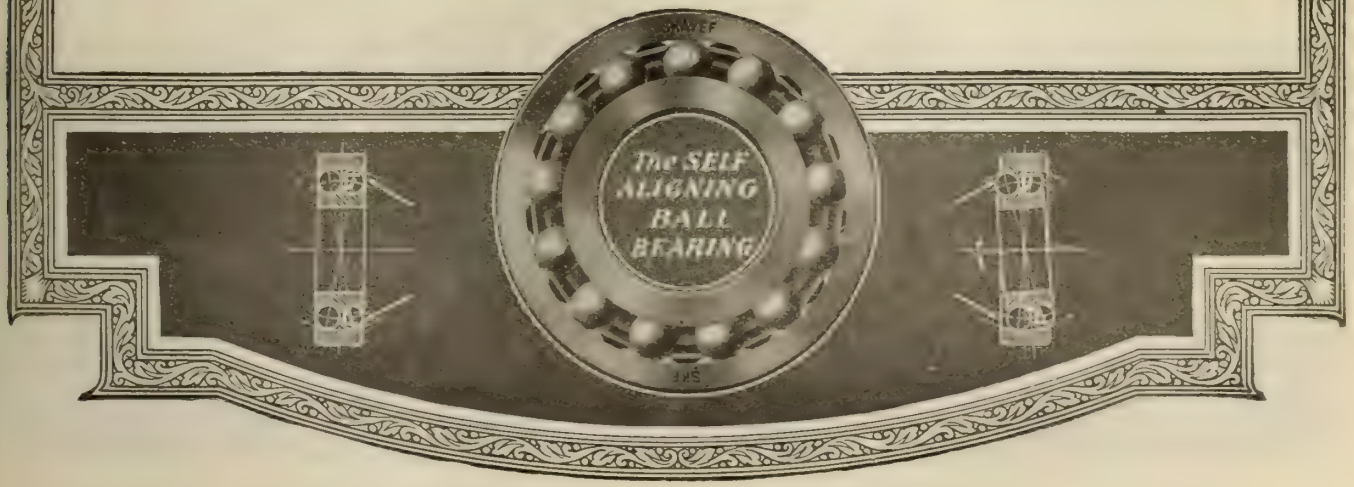
SKF

Rotor Shafts of Mining Locomotives
Can't Wear When Ball Bearings Are Used

ROTOR shafts mounted on **SKF** marked self-aligning ball bearings do not come in contact with wearing, rubbing surfaces. Instead, two rows of accurate steel balls which separate an inner and outer race take all the load and resist friction and wear, with an oil film needed only to retain the bearing polish. Note the construction of the ball bearings shown above, and the inner races which revolve with the rotor.



The modern method of mounting mine-locomotive shafts eliminates many motor failures. It provides sealed bearing housings which prevent dust and grit from working in. It displaces plain-bearing installations which permit shaft and bearings to come in direct contact the instant the oil film breaks, thus setting up a wearing, rubbing action which soon causes burnt-out armatures and breakdowns. These troubles frequently occur when locomotives are far underground where they are difficult to get at and work upon.

Keep the armature from dropping on to the pole pieces — save the rotor windings from damage — by installing **SKF** marked ball bearings.

Our Engineering Department will be glad to explain in detail how these ball bearings eliminate the many elements of motor destruction.

Costs Reduced By Systematic Piling of Goods

Unproductive Labor Effort Should be Controlled—Careful Planning of Storage Space Needed—Convenience and Accessibility Two Important Features—Reducing Manual Effort

By J. H. RODGERS

MANUFACTURING plants of every description are continually confronted with the problem of non-productive time. The character of the elements that make up the total period of this seemingly ineffective effort are often varied and difficult to control but the greater mastery that is achieved in this direction results in an increased balance being shown on the right side at the close of the year's business.

Every detail in connection with the making and marketing of any article is, invariably, essential to its production and distribution. Doubtless there are many incidentals that could be modified, and in some instances, entirely eliminated, but in general every operation, both of a productive and non-productive nature, is needed, more or less, in getting the article into the consumer's hands.

The handling of material both in semi-finished and finished condition is an item that cannot be directly charged to each individual piece manufactured, but the cost must be distributed over a production period of a definite number of months or even years. This handling of goods includes the acceptance of the raw material when shipped in to the plant, its removal from the cars or trucks, its sorting and piling in stock yards or store rooms, the piling and arrangement of the different commodities in readiness to being transferred to the various departments for machining and assembly. Handling also includes the transferring of the semi-finished work from one machine to another, or from one department to an adjoining one and the subsequent delivery to the shipping room, and finally, the placement in cars or trucks for distribution to customers.

Where manufacturing is carried on in a big way and large quantities of raw materials are required, it is essential that ample space be available for the piling of stock. In this respect it is advisable, and likewise economical, to arrange the stock bins or compartments so that only one class of material is contained in each. In this way it may be necessary to provide more space than seems permissible but the conservation of time when delivery is requested will offset any apparent disadvantage of excess yard room. The installation of a crane of suitable capacity is an imperative necessity where heavy material is to be handled, as this is the most convenient method where heavy stock and plant equipment are temporarily stored.

Another important feature in regard to transferring material from the yard to the shop is the relative location of the shop crane to that in the yard. These should overlap in such a way that articles deposited by one crane can be taken up by the other in a straight lift. If an angular lift is made the movement of the material when it leaves its position of rest will result in a swing that may cause serious injury to equipment or workmen. When a crane cannot be located directly over the piece to be elevated, it is always necessary to caution nearby workers, and the interference thus occasioned results in adding to the unproductive time. Not only do such conditions disturb the employee but the thought that danger is imminent often makes it necessary to provide protection to tools he is using, the removal and replacement of which requires time that might otherwise be saved or used in productive effort.

The fundamental idea of manufacturing is to produce on a basis that will give satisfaction to all concerned and at the same time show a profit on invested capital. Successful management means that harmony prevails in all departments. A handicap should not be placed on any individual or department whereby that person or section of the plant must stand aside while the regular duties of others are being carried on. It is seldom that ideal conditions can be established in a factory but it is often well worth while to strive to at-

Fig. 1.—Showing neatly arranged stock warehouse of the Marshall Wells Hardware Co.

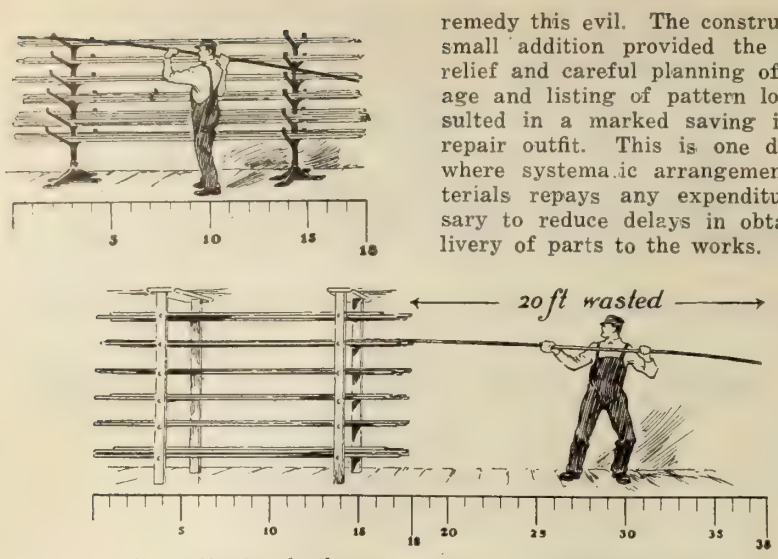

Fig. 3.—Showing the floor space saved by use of open side racks.

tain a higher state of operating efficiency.

One of the greatest sources of wasted time is in the delay often resulting from delivery of material from the storeroom or stock pile to the manufacturing departments. The cause of this may frequently be laid to the inconvenient manner of piling or storing of parts. The writer has in mind one particular instance where a fair sized foundry had only a comparatively small yard in which to store their supply of moulding flasks, and no adequate provision for transferring them to and from the factory. When a fairly large flask was required it was necessary for the moulder and several men to go and dislodge the particular flask they desired. Since that time additional property has been acquired and the yard equipped with a travelling crane and the flasks and other equipment so piled and arranged that a minimum amount of time is required when requisition is made for such material; one man only needs to go to select the piece wanted.

This same firm had many thousands of dollars worth of patterns stored in a loft above the pattern shop, but owing to the growth of the business and the relatively rapid accumulation of patterns the storage space provided was quite inadequate, the consequence being that this department was far from being efficiently conducted. Some attempt was made to regulate the placing of the various patterns but with little real success. When a pattern, that had not been used for some time, was wanted it was generally found that it was not in its accustomed place or that it had been completely covered by others used more frequently. The method usually followed was to take those on top and—none too gently—toss them aside until the one wanted was secured. This practice was more common with the smaller patterns. The maintenance cost, however, on patterns damaged in this way, gradually impressed the superintendent that something would have to be done to remedy this evil. The construction of a small addition provided the necessary relief and careful planning of the storage and listing of pattern location resulted in a marked saving in pattern repair outfit. This is one department where systematic arrangement of materials repays any expenditure necessary to reduce delays in obtaining delivery of parts to the works.

The view shown in Fig. 1 is that of the general warehouse of the Marshall Wells Hardware Co. at Portland, Oregon. This shows a well arranged storehouse where accessibility is one of the outstanding features. The wide assortments of plates are so stocked that one or more of any particular size or gauge can be obtained without disturbing any other plates. Bars are arranged in a similar manner as can be seen at the extreme lower left. Individual racks are provided for each grade and size of bar. The upper deck is subdivided into compartments for the storing of pipes and tubes and so arranged that tubes can be lifted vertically by the crane and delivered to transfer trucks. Pawling and Harmischfeger 5-ton cranes are installed in this building. The hardware firm has found that they can effect big savings in handling material of this description. This is made possible through the reduced labor cost of handling and also because a greater quantity of goods can be piled in the space available and done so with great convenience. Emphasis is also placed on the fact that mechanical piling assures quicker service to the plant or the customer.

Fig. 2 shows a large foundry with a comparatively small yard space, but systematic piling and a P & H 25-ton crane provides sufficient facilities for storage purposes.

Handling of goods is often economically performed by means of conveyors. Where continual movement of articles or material is taking place this practice is found to be of great service as it practically eliminates all labor of transportation purposes, workmen being required only for the placing on and removal of the parts. Much saving of time is effected in this way.

Accessibility is one of the outstanding features of efficient storing or piling of material and equipment. This is especially true where it is necessary to secure the parts many times every day. Careful planning of storage racks in a plant will not only save manual effort and time but will also furnish a means to greater production. The sketch shown in Fig. 3 is a clear way of illustrating this. A common method is to provide closed racks as shown in the lower view, where it is necessary to provide space for withdrawal of the bars equal to their length. The upper view shows the Brown type of stock rack, made in sectional form where the minimum amount of floor space is required for piling and removing the bars. Considerable time can be saved when racks of this character are located alongside such machines as turret lathes and automatics. The advantage of a rack of this kind is that it can be made to accommodate a variety of bars of different materials, and may be located in any place and moved if desired, as the base is so constructed as to be self-supporting.

In planning storage facilities the chief features to consider are those of convenience and accessibility, as they accelerate the movement of material and reduce the unproductive time.

In screw thread practice the term lead is generally understood to be the distance which the screw advances in one turn. The pitch is the number of threads cut in one inch of length, on any given diameter.

Fig. 2.—Convenient piling made posible by means of overhead crane.

House Cleaning In The Industrial Plant

Keen Competition Means That Every Possible Source of Waste Should Be Eliminated—Importance of Daylight—Clean Cheerful Shop means Better Work—Systematic Arrangement Brings Best Results

By G. A. KUECHENMEISTER
Personnel Manager Dominion Forge and Stamping Co.

THE USUAL spring epidemic of house cleaning is once more with us, and has taken a firm hold of the housewives of the country. There will be dust flying, much scrubbing and delving into rubbish heaps and dark corners. The supposed boss of the house comes home expecting a quiet rest in his favorite chair, but finds windows wide open, rugs on the line and furniture piled up in one room.

Spring house cleaning is a necessary part of housekeeping but, as it was formerly known, it is fast disappearing. The vacuum cleaner and other modern home conveniences are changing housekeeping methods and the tendency is away from the old idea of setting aside a period of days each year to revel in the joy of upsetting the entire household.

With the housewife who still clings to the old broom and duster we have no argument. It is her home and she is boss, and if she wants to make life miserable for the men of the house for one or two weeks each year, that is her business, but when a plant manager or superintendent takes the stand that it is not economy to spend money to keep the plant clean from day to day and week to week, we are ready to argue; and it can be argued from the standpoint of safety, health, efficiency and production.

There may be plants still doing business where it is possible to throw raw material, material in various stages of fabrication, supplies of all kinds, cuds of tobacco and rubbish into all the dark corners of the shop and show a profit at the end of the year but, with competition becoming keener each month, the wise man will dig up every penny's worth of material and turn it into the finished product and get cash for it.

To do this it may be necessary to adopt the housewife's method of turning the whole works upside down and getting into the dark corners. If that is the only way to get started the sooner it is begun the better. Many a shop has been turned from a junk heap into a clean, up-to-date plant by installing a proper lighting system. Getting light, daylight or artificial, into the dark corners shows us up, and shames us into keeping the place clean.

Most plants have plenty of windows. When they are first built they are roomy, cheerful, airy places and the owners are congratulated on the splendid building. A year later it is often difficult to recognize the place. The simple process of washing those windows and putting new glass in place of the old rags and sheet metal that have replaced broken panes in the sash, will restore the bright appearance of the place. It makes a good beginning for the cleaning job.

After daylight has been let into the plant the true condition of the place is easily seen. All hands, men and boss, can now be used to good advantage. The boss can tell at a glance whether the material found in the corners is of further use, whether to send it to the store room, to the junk dealer, or what other disposition should be made of it, and the men can put it there.

Right here is the determining point in shop cleanliness. Unless there is a definite place for every article—and scrap, broken machine parts, etc., all need consideration—and unless every man in the plant, responsible for its disposition, knows where each article belongs, there will always be a moving of junk from one place to another. Bins for turnings, castings and other scrap and a platform for broken machine parts can be built in any plant, no matter how small it may be, and are worth many times the cost of construction.

Constant Reminders

These bins should be put right out in the open where the manager and superintendent cannot help but see them. They will be constant reminders and tell-tales of what is being thrown away. The platform for broken machine parts is a real help to the manager. With broken parts up out of the dirt in broad daylight they tell the story of what is going on in the plant. These same bins and platforms also make it easy to dispose of scrap and broken parts to the junk dealer and prevent the selling of much valuable material at scrap prices.

A dark store room is a catch-all for the rubbish of the shop and since it is easier, in many cases, to write a requisition for new material than to dig out the stuff from the bottom of a junk pile in a dark, foul smelling store room, it very frequently happens that a lot of money is kept tied up in supplies.

Especially is this true of store rooms for mill-wright supplies and repair parts. This can be overcome by using wire screen for the walls around the store room. Get the thing wide open so that anyone walking by can see what is inside. It has a wonderful effect on the cleanliness of the place.

Assuming now that you have thoroughly cleaned-up, scrubbed-up and painted-up—and if you have followed the housewife's plan of turning everything upside down and gotten into all the corners with the broom, mop and paint brush—then is the time to solemn-

The efficiency of this foundry was greatly increased by giving the walls a coat of white enamel.

ly raise the right hand and vow, "never again."

Keep it Clean

After an analysis of the whole proposition of maintaining a clean, light, cheerful shop you will find nothing to prevent you doing so. Windows can be kept clean at a low cost. For the small shop it will only require part time of one man to watch them and keep them clean. For the big factory with thousands of lights, a window-washing crew will pay its way. Some factories have worked the thing out on a piece work basis and are keeping the windows clean at a remarkably low cost.

If "light is a tool that makes every other tool more efficient" then surely the money spent to let in the glorious sunshine and help increase the effectiveness of all the tools in the shop, is well expended. Artificial light can also be used to mighty good advantage. If the plant is wired in the hapazard fashion of olden times it is well to have an "illumination survey" made. Properly placed lamps with the right style reflector will help the workmen at their work and will also show up the corners that are likely to be used for rubbish storage.

One-half of 1 per cent. of a man's wages—2½ cents per day for a five-dollar-a-day man—will pay for the installation and power consumption of a proper lighting system in any factory. But electric lamps put into a socket and then allowed to gather a coat of dust and dirt will grow dimmer and dimmer—and continue to consume the same current. The same electrical helper who put them in place can usually find time to keep them clean if ordered to do so.

Then, there is a matter of sweeping and removing waste material. It is not something that can be done once in a while or once a year. It is with us every day in the year and upon the successful solution of the problem depends the cleanliness of the shop.

In the large plants suction systems and well organized corps of cleaners can be installed and maintained, but in the small or medium sized factory there always arises the question of just how much money can be spent in keeping the place clean.

Supervision Necessary

There again we can use the comparison of the housewife who is determined to keep her home clean. If she allows us to drop clothes and other articles wherever we happen to be or if she never complains about the appearance of the wash bowl or bath tub after we have used them she will wear herself out in a few years doing what we have thoughtlessly forced upon her. But if she is on the job and supervises the placing of clothes and the cleaning of wash bowls it will be comparatively easy for her to keep a clean house. With the help of a woman once a week or twice each month the home can be kept so that the old fashioned house cleaning will not be necessary each spring.

And so it is in the plant. With a sweeper in each department or one for several departments devoting his entire time to keeping the place clean and with the workmen ordered to throw waste material not into the corners but into bins or at least into the open from where it can easily be removed, there is no need for a shop to get into a filthy, unhealthy condition. Laborers and yard men—even the truckers—can help keep the aisles clean and clear of rubbish and it will all make for a safer, healthier, happier shop.

In plants which are particularly difficult to keep clean because of manufacturing conditions it may be well to adopt the "woman once a week plan." Shops that are operating five days a week can use Saturday mornings to do the extra cleaning and under present industrial conditions Saturday afternoons can be used for the work without greater cost than on other days.

Every factory or shop has its own peculiar problem, but each and every problem can be solved. The burden of solving the problem of maintaining a clean house falls upon the "housekeeper"—the big boss. If he wants it clean he can have it clean and it need cost only a fair share of the overhead of the plant.

Cleanliness a feature of this mill room.

THINKS OUR VIEWS ABSOLUTELY CORRECT

By David James

YOUR recent article and editorial on the noon hour problem appearing in April 27 issue is a very timely one. As I write this I can look through the office window and see the men and boy coming off the football field with the sweat streaming down their faces. Some of them in a state of exhaustion from the strenuous game, or perhaps I should say "rough house" they have just been indulging in. Now anyone knows that this state of affairs is a bad thing from every view point. To indulge in such violent exercise immediately after dinner, must have a bad effect on the men themselves to say nothing of unfitting them for duties for an hour or so. I wonder what would happen if the firm were to ask for such strenuous exertions? To my mind a cafeteria run on a non-profit basis is certainly a great boon to the worker.

There are many workers who live about 20 minutes walk from their work. Whether they use car, bicycle, or walk it uses up a large amount of nervous energy which a well-ordered cafeteria would avoid. A rest and reading room with comfortable chairs, not a straight backed bench made up in a hurry at the carpenter shop, would be a great benefit. A few trade papers and newspapers with an occasional lecture or musical entertainment for half an hour would be a great asset. I have seen several shops where the game of checkers was introduced and it had a beneficial effect as the apparently simple game of checkers is a great brain trainer. This simple little game is ever new and none have fully mastered all its intricacies. Or, if the weather is such that you feel you must be out of doors, nothing could be better than a large bowling green. It is a fine skilful game, cultivates good comradeship and is an added beauty to the environments of the factory.

Let us have welfare work at all costs, but let us conduct it on safe and sane lines and those lines should tend toward the developments of the mental rather than the physical.

The addition of a small percentage of silicon to nickel shot produces a silicon-nickel shot which is said to be superior in many ways to other materials now in use. A new method of polishing and burnishing metals with the tumbling process has been developed. Nickel-silicon shot is used in this process and is said to have the advantage of longer life, does not corrode, always remaining bright and clean. It may be used in conjunction with acids in which case it removes scales; the polishing water does not become dark or slimy, rendering articles difficult to clean after polishing. It is non-magnetic and therefore can be used in process using magnetic tumbling barrel for iron and steel articles.

Overhang of Work Affects Machine Accuracy

Unusual Jobs Require Special Methods of Machining—Arrangement of Work Should be Carefully Considered—Counterbalancing Good Practice—Avoid Excess Strains in Machine Parts

By J. HENRY HAMIL

WHEN a job comes along that is beyond the normal range of a machine it is the general practice to adopt some impromptu method of performing the work. Few men like to admit that they cannot handle the odd job and it is only an exceptional case where work is turned away for the reason that it is beyond the capacity of the shop. Not only is this true of the ordinary jobbing shop but very often the same conditions apply to the manufacturing concern accustomed to doing regular lines of work. It is often remarkable the class of work that is sometimes undertaken and successfully accomplished in cases of emergency when the plant superintendent or foreman, or even the workman, is endowed with the necessary initiative.

In planning work out of the usual run of the shop, the actual performance of the required machining is not the only matter that should be given consideration. Too frequently, when doing work of unusual character the workman is liable to neglect to take into account the resultant effect upon the parts of the machine performing the work. All tools are designed to function properly within their specified range and when required to go beyond this limit stresses are created that were not figured on in the building of the machine. Therefore, it is always advisable to determine, as far as possible, what will take place when abnormal work is being machined.

Cause of Strains

In some cases the machine may be operating inside the working range, but due to the shape of the piece being machined certain sections of the tool may be subjected to temporary stress which eventually may seriously affect the accuracy of the movable portions. The proper distribution of weight is the most important detail in connection with the machining of work, especially when the latter is required to move while the tool is cutting the metal. When a heavy casting or forging rests upon the table or bed of a machine the table should move almost as freely as when loaded with a lighter weight. The slides should be well lubricated and if possible the weight located so that centre of gravity is as near the centre of motion as is convenient to perform the necessary operation. This, however, is not always possible, for if it was we would probably be working within the machine range.

Special Practice

The unusual job calls for unusual methods and it is because it is out of the ordinary that other facilities than those generally adopted have to be applied to meet the changed conditions. Out of range work is that where the work is extremely large or exceptionally long. We recall a job some years ago where, in order to accomplish the work, it was necessary to raise the head stock of a gap lathe about six inches. The lathe was fitted with ordinary change gears and an auxiliary stud was made for connecting the train. The job was the frame and trust ring—the latter 7 ft. dia.—of a large tire setter. This had to be mounted on the face plate but trouble was experienced almost before the tool was advanced to the work. The rear cap bearing screws failed to hold and it was only because the ring was just clear of the floor plate that serious damage was prevented. Repairs were made and to assist in sustaining the alignment of the spindle a heavy scantling was placed between the rear bearing and the ceiling. The work was started but excessive chatter necessitated the delay of a day or two while rollers and brackets were made and located on the floor plates to take the excess weight of the ring and heavy portion of the frame, which together weighed over one ton. With these fitted in place no further difficulty was experienced.

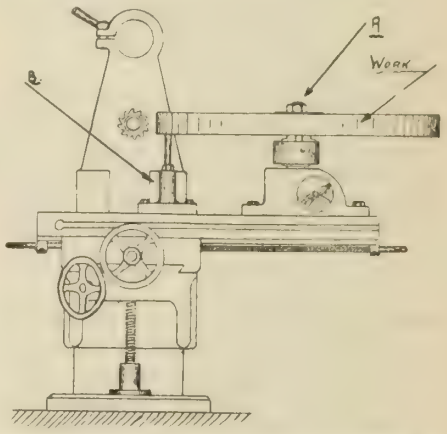

Fig. 1.—Overhang should be counterbalanced by suitable weight.

Die Sinking Job

On another occasion we had a large die to sink and were forced to use a small die slotter and miller that was considerably below that on which the work should have been performed. It was first necessary to make an auxiliary plate to act as an extension to the regular table, to provide adequate support to the work. After struggling with the feed screws for a short time it was decided to adopt some method of taking care of the surplus weight. Owing to the constant movement of the work, both vertically and horizontally it was impossible to provide a floor support, so it was decided to locate a small grooved pulley in the ceiling over which a small cable could be used. The counterbalancing weight was located at the rear of the machine where it did not interfere with the movements of the operator. It was found that the slides moved almost as freely as when working without load. The cable and counterweight became a permanent accessory of the machine and was used advantageously many times.

Cutting Large Gear

A typical example of excessive strain caused by overhang of work is shown in Fig. I. This illustrates the cutting of

(Continued on Page 23)

Fig 2.—Showing where counterbalance would work to advantage.

Greater Production by Use of Special Fixture

Device Attached to Turret Operated from Overhead Shaft—Wide Face Machined by Short Tool Movement—Appliance May be Adapted to Various Purposes

THAT the efficiency of turret machines can be greatly increased by the use of special fixtures is shown in the accompanying illustration. This attachment has been placed on the turret of a Libby lathe and is operating successfully at the automobile plant of the Studebaker Corporation. The device is designed for the purpose of facing and forming fly wheels, flanges and discs, the object being to machine a wide area by a relatively small travel of the cutting tools. As can be seen from the illustration the appliance is driven from a special countershaft overhead by means of a telescope shaft, this being necessary owing to the lateral movement of the turret head.

The line drawing gives some idea of the construction of the device. The shank, which also carries a steady bar, is clamped in the turret in the usual manner, a portion of the bar, B, being cut away to allow of vertical travel of the tool slide. The body of the fixture C, which extends above, carries the feed screw, D, keyed to which is the large worm wheel, E, and the hand wheel, F. The worm wheel is driven by the worm, G, this in turn being operated through a train of spur and bevel gears from the overhead countershaft. The screw, H, operates in the bronze nut, J, the thrust being taekn by th eball bearing, I. The nut, J, is fixed to the tool slide, K, the fan of which is slotted to receive the various cutting tools.

The left hand view of Fig. 2 shows a horizontal section through the driving gears. The telescopic shaft, M, carries a two-way clutch that may be engaged with either upper or lower bevel gear, N, to mesh with gear, P, the clutch lever being shown at O. On the rear of the shaft, Q, is the small spur gear, R, that meshes with gear, S, on the worm shaft, T. For hand feeding the worm may be disengaged by movement of the handle, U, which, in a power feed position is held in place by the lathe, V. This is clearly shown at the front of the fixture in Fig. 1. A sketch of the piece being operated on is shown in Fig. 3.

CRANK SHAFT GRINDING

When the plain cylindrical grinder is applied to crank shaft grinding the grinding wheel encounters one of its hardest tasks. The wheel is fed direct to the work, and in order to grind the fillets it must hold up on the corners. The condition of the pins and the finish required determine the grit and grade of wheel to be selected for the job. A cam shaft is another instance of the wheel engaging the full width of the work. For grinding automobile and aircraft cylinders special skill is demanded.

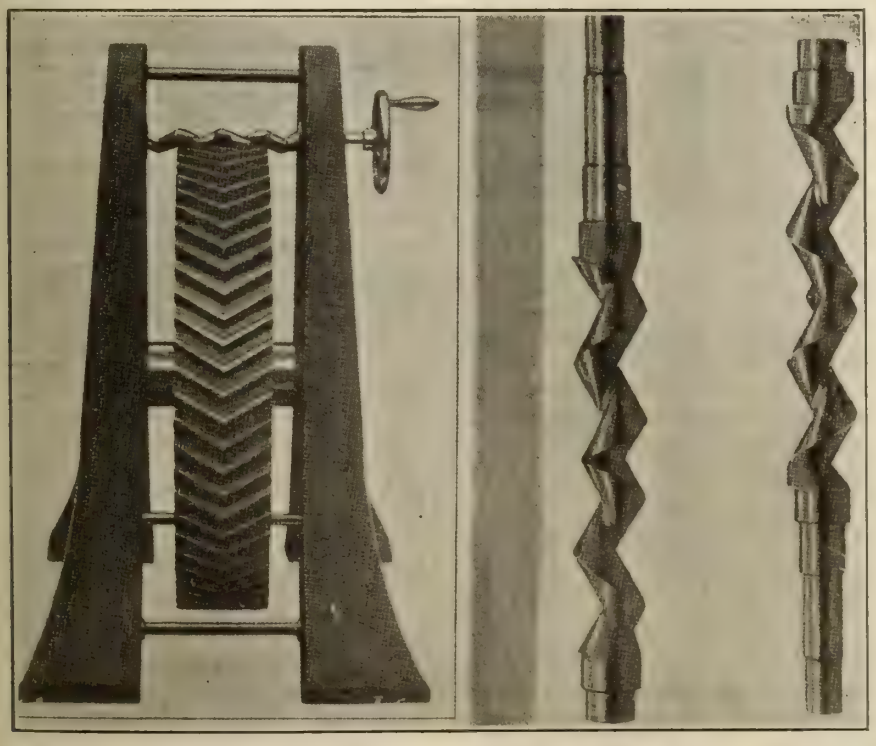
Maximum Speed Reduction By One-Tooth Pinion

Interesting Method of Tooth Formation—High Working Efficiency—Perfectly Uniform Motion—Deflection Remains at Low Limit—Slight Sliding Action on Teeth

SPEED reduction in gearing has always been a problem to mechanical engineers. To obtain a great ratio it has been necessary to use a system of gearing, owing to the fact that it was inadvisable to utilize pinions with a small number of teeth. The double helical gearing here illustrated and described, in which a pinion of one tooth is the essential feature, will be of special interest, not only to the student and those on experimental work, but, as stated in The Engineer, the makers, the Power Plant Co. of West Drayton, Eng., claim that it will be of wide practical utility.



The particular example shown will shortly be placed in the South Kensington Museum, while a similar set will be made and put into actual service by the company. Under a power test over a considerable time the gearing transmitted 10 horse-power at a pinion speed of 1000 revolutions per minute without showing any signs of wear. With the pinion as the driver the makers believe that the efficiency is as high as that of any other double helical gearing, that is to say, that it is probably between 97 and 98½ per cent. In this connection it may be remarked that the gearing is said to work satisfactorily with the wheel as the driver. As for its practical utility, it is pointed out that it is much more compact, more efficient and cheaper to produce than double-reduction gearing of the same ratio.

The production of a one-tooth double helical pinion such as that illustrated has only recently become possible.

The example shown was made on a Sykes No. 4 patented generating machine with standard equipment and cutters. The same machine and the same cutters were used for producing the wheel. The teeth of both the pinion and the wheel are continuous, and at the junctions of the right and left-hand portions there is no departure from the true involute shape.

In order to obtain very high gear ratios, straight-tooth pinions with three teeth have been used in the past. With helical teeth, however, it becomes practicable to design the pinion with one tooth in such a way that the transmission is positive and perfectly uniform. In contrast with a high-ratio worm gear drive the one-tooth helical pinion and wheel should show a greatly increased efficiency.

The example illustrated has a ratio of 63 to 1, since the wheel has 63 teeth. Other data connected with the design are as follows:—Pitch circle diameter 0.508in. pinion, 32.004in. wheel; Outside diameter 1.756in. pinion, 32.210in. wheel; diameter of shaft 1½in.; pitch 1.968 D. P. or 1.595in. circular pitch.; face width 6in.; centre distance 16.26in.; pressure angle 22 deg. 10 min.; ratio of pitch diameters 63 : 1; ratio of outside diameters 18.28 : 1.

Left—One-tooth pinion meshing with large herringbone gear. Right—Two views of one-tooth pinion.

It will be noticed from the line engraving that although the pitch circle of the pinion is only a shade over half an inch in diameter, the abnormally large outside diameter gives the pinion a section which—or so it is claimed—is such as to enable the gearing to transmit the designed power without undue deflection. The action of the tooth contact is almost entirely of the "recess" kind, that is to say, it takes place when the pinion is going out to engagement with the wheel. This condition, it is claimed, promotes efficiency and assists good lubrication, because it results in the oil being drawn into the line of contact. It has been suggested by some engineers who have examined the gearing that there is excessive sliding action between the teeth. The makers contend, however, that the results of the test on the gearing prove that whatever amount of sliding action there may be is not harmful, and that, providing such action takes place in recess, it is apparently an advantage.

OVERHANG OF WORK AFFECTS MACHINE ACCURACY

(Continued from Page 23)

the teeth in a large gear on a small planer, described in a recent issue of Canadian Machinery. It will be quite obvious that the table slide is under considerable stress when working under these conditions, and the vertical movement necessary in cutting the teeth will demand extra pressure on the lower portion of the right slide and on the upper end of the left. Of course, it is realized that this is an exceptional case but at the same time it is a condition that affects the general accuracy of the machine and one that should be avoided whenever possible. In this particular instance the overhang could have been neutralized by using a counterbalancing device of some kind.

Another example of overhang is illustrated in Fig. 2. Here an extension has been placed on the front of the milling machine knee to provide a pivot for milling the proper arc on a piece of work. Another case where the strains could be minimized by proper counterbalancing.

Experience has shown that for steel and annealed malleable iron the aluminous abrasive wheels should be used and that for gray iron, brass, bronze and unannealed iron, silicon carbide wheels should be used. Aluminum castings are snagged successfully with both types of wheels.

News From the Welding Field

Overcoming Defects and Failures in Welding

Allowance Must be Made for Expansion and Contraction—Methods of Eliminating Distortion of Welded Parts—Causes and Remedies—Making Calculations in Advance

By M. PIETTE

IN ALL cases where bodies are subjected to alterations of temperature, expansion and contraction must be constantly taking place. Although in many cases this effect may be ignored it is of the highest importance in welding operations to make proper allowance for their effects and to take such steps as will reduce the effect to a minimum.

One of the greatest difficulties to be contented with in welding is the control of expansion and contraction due to differences in temperature of different parts of the piece welded. In the case of ductile materials, like iron and steel, warping, distortion or buckling will inevitably take place if expansion and contraction are not properly allowed for. In non-ductile materials, such as cast iron or materials whose strength are low when near the melting point, as for example aluminum, aluminum alloys and copper, the strains produced may cause the metal to crack or fracture. Further in many cases although distortion or fracture have not taken place the expansion and contraction effects have produced serious internal strains which only require a slight addition to exceed the strength of the metal and thus produce failure. It is for this reason that many welded articles which appear to have been successfully welded prove to be failures shortly after being put back into service.

In this series of articles, it is proposed to deal with the subject of expansion and contraction mainly with regard to the distortion and warping effects commonly observed in welding iron and steel, and to explain their causes and remedies in such a manner that the beginner, who is usually discouraged by the surprising effects he obtains with the blowpipes, may easily understand the phenomenon accompanying expansion and contraction.

Expansion and Contraction

It is necessary to repeat over and over again to welders that it is useless to attempt to arrest or control by force the expansion of metals raised to a high temperature and which return more or less to their original dimensions when the heat, which has produced the expansion, diminishes and finally disappears. In other words, the forces of expansion and contraction are irresistible and if attempts are made to control them by force—the use of clamps, jigs, etc.—distortion, serious internal strains, or failures will result. Everyone is familiar with the fact that this property of expansion and contraction is taken advantage of in engineering such as, for example in the shrinking of tires and angle-iron rings and that it has to be allowed for in railway lines, casting, steam-pipe joints, girders.

When metallic bodies are heated they expand in every direction; and conversely a decrease in temperature causes the bodies to contract and the volume and linear dimensions decrease. In many practical cases we are only concerned with the increase in length. Increase in length is referred to as "linear" expansion, and increase in volume is called "cubical" expansion. Metals are very susceptible to this change in volume, each metal, for a definite rise of temperature, expanding a known amount. It is convenient to calculate the amount of expansion to be expected from a rod of the metal of unit length when it is raised through one degree of temperature. This amount is called the "coefficient of linear expansion" of the material. It is easy to see that—Coefficient of Linear Expansion =

$$\frac{\text{Increase in length produced by Rise of Temperature}}{\text{Original length} \times \text{Rise of Temperature.}}$$

In dealing wtih cubical expansion the word "volume" is substituted for length.

From the following table it will be seen that the coefficient of linear expansion is always a small number.

Metal	—Coefficient of Linear Expansion.— per degree Cent.	per degree Fahr.
Wrought Iron ..	0.0000125	0.0000069
Cast Iron	0.0000107	0.0000059
Steel	0.0000113	0.0000063
Aluminum	0.0000231	0.0000128
Brass	0.0000188	0.0000104
Copper	0.0000168	0.0000093
Lead	0.0000292	0.0000162
Nickel	0.0000128	0.0000071

The amount of expansion for 1 degree Fahr. is 5-9 of that which takes place for 1 degree Cent. The figures in column 3 are therefore 5-9 of the corresponding figures in column 2. The values given in the table represent the average coefficient between 0 degree and 100 degrees Cent. At higher temperatures the expansion of metals is not directly proportional to the rise of temperature. Of the metals most commonly welded it will be noticed that lead expands the most, aluminum next, then brass, copper, nickel, wrought iron, steel and cast iron. It will be seen that aluminum expands almost twice as much as iron or steel.

Force of Expansion

Although the amount by which most substances expanded for a rise of one degree is very minute yet the force exerted by the metal on expanding is considerable and, as already mentioned, will, if resisted in welding operations, easily distort or lead to the fracture of the expanding body. The actual force brought into play during expansion can be calculated from the fact that it is equal to the force required to stretch the material, mechanically, by the same amount. Suppose a bar of length l is heated t° Fahr. and c is the coefficient of expansion of the material. Then unless prevented, the length of the bar will become $l(1+ct)$, that is the increase in length will be $c\,t\,l$. If the bar is rigidly fixed so that the expansion cannot take place, then there will be in the bar a strain equal to $c\,t\,l$. This strain will produce a compressive stress equal in the case of mild steel to a stress of 0.085 tons per square inch for each degree of temperature. Taking a range of temperature to say 150° Fahr., which is very low, the stress due to temperature is equal to 1 275 tons per square inch. This is greater than the safe stress for mild steel. In other words, if a bar ½ inch in diameter is heated through 150° Fahr. the force exerted as a result of the expansion effects is equivalent to 65 tons. This simple calculation should bring home to the welder the enormous forces which are capable of being brought into play as a result of expansion not being properly taken care of.

For calculating the deformation brought about by contraction effects it is useful to know what contraction usually takes place when certain metals have been welded and the line of welding subsequently cools down. The following are the usual shrinkage allowances for each foot of length:

Paper prepared for Acetylene Journal by the author, who is engineer to the Chamber Syndicate de la Soudure Autogene. The material has been translated and added to by Capt. D. Richardson, R.A.F.

Cast Iron—thin material = 1/16 inch
Cast Iron—thick material = 3/32 inch
Steel ..... = 1/4 inch
Copper ..... = 3/16 inch
Malleable Iron ..... = 1/5 inch
Aluminum ..... = 1/5 inch
Brass ..... = 3/16 inch
Lead ..... = 5/16 inch

Consider for a moment that two plates are to be united by a line of welding. The edges of the plates may be or may not be bevelled. It is always necessary to raise to the melting point a length of metal which, in the case of plates that are not bevelled, consists mainly of the edges of the plates, and in the case of bevelled plates is supplied by the filling material or welding wire. In both cases, the result is the same, a certain volume of metal is melted along the line of welding and on cooling becomes integral with the parts welded..

It is easy to comprehend that if it were possible to raise the whole line of welding to the melting point at a particular moment the length of this line would depend upon the coefficient of expansion of the metal and, on cooling, a contraction would take place which would equal the amount of expansion; the final length of the line of welding would always be equal to that of the line of welding before the operation. In this case there should be no deformation of the plates in a longitudinal or transverse direction. Unfortunately, in obtaining welds with the blowpipe the conditions described do not take place because the line of welding is obtained by a successive series of small molten baths which cool off as the work proceeds so that the phenomenon of contraction and expansion is taking place continuously in small sections and it is this factor which brings about distortion and warping of the plates.

In considering the effects of expansion and contraction in welding operations it is necessary to thoroughly grasp the fact that the line of welding, made in the usual way, is shorter after welding.

Size of Weld

The size of a weld also plays an important part in distorting or warping the parts as they cool. The shape and size of the molten bath constituting the weld, varies with the thickness of the metal. Its size and shape can be clearly brought out by means of etching tests.

In Fig. 1 the welded zone is clearly

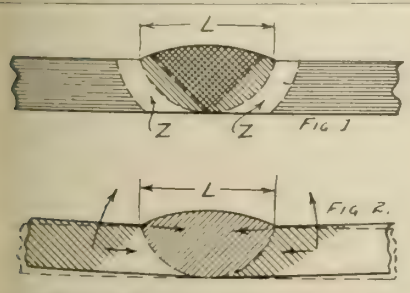


Fig. 1.—Welding zone clearly shown.
Fig. 2.—Showing warpage effect.

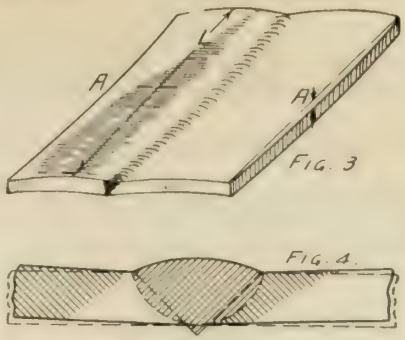

Fig. 3.—Final shape of plate.
Fig. 4.—Effect of contraction.

shown and, during the welding operation, the length of the base line of the "B" increases to the dimension and L consists of metal which has still to cool down and consequently to contract. It is also necessary to consider the contraction effects of the two zones Z and Z situated on either side of the bevelled faces. These zones, at the moment of welding, are expanded and on cooling will contract so that this contraction effect must be added to that of the molten bath itself.

The result of these two contractions is to produce a warpage effect as shown by full lines in Fig. 2. The final shape of a plate with a longitudinal weld is shown in Fig. 3. The contraction effects mentioned bring about the results (1) a shortening in length of the plate as measured along the line of welding produces a convexity at the edges A, A (2) the transverse contraction of the molten bath and surrounded zones produces a very obtuse angle, in other words the two parts welded together are not in line.

It is easy to calculate the longitudinal contraction of a line of welding but the determination of the transversal contraction, with its resulting deformation, is practically impossible for several reasons. In the first place the contraction is not confined to the surface of the bath but extends throughout the mass of melted metal. It is for this reason that overlapping of the edges takes place where the plates are not tacked or sufficiently separated. This contraction throughout the mass is shown by the distortion at the lower edges of the bevelled faces which, as a result of the very high temperature, are strongly pressed against each other under the contraction effects of the preceding portion of the weld in process of cooling.

Effect of Contraction

Fig. 4 shows this characteristic effect of contraction on the lower edges of a joint. The dimensions of the plates, on each side of the weld, have an influence on the contraction effects, not as a result of conductivity, which is small, but in consequence of its mass or weight which tends to resist the contraction of the molten bath and diminishes to a certain extent the effects of contraction. The net result is to increase the value of the internal strain in the mass of solidified metal. This is verified in practice as one finds that in welding plates of the same thickness and under the same conditions, that the angle formed by the two plates after welding is less in the case of large plates than in small plates such as, for example, test pieces. The distortion and warping effects consequently are proportionately less in thick plates than in thin plates.

The question arises as to whether it is possible to calculate in advance the value of the deformation which will be produced. In certain cases, when welding horizontal plates or tubes, for example, where the linear contraction is known, it is possible to determine the deformation. In the majority of cases, however, it is impossible because a whole series of factors intervene which influence and vary the effects of contraction in the welded pieces. The method of welding may, for example, vary from one shop to another, the thickness of plate, the welding with or without bevelling, the angle formed by the blowpipe used, blowpipe manipulation, the direction of the flame, the degree of penetration, the speed of welding, the internal shape of the molten bath, whether backward or forward welding is applied, the overcharging of the weld, stoppages during the welding operation, etc., are the main factors that influence the contraction effects.

It is not possible, in the majority of cases, to apply the results which have been obtained on simple pieces welded in large quantities. On the other hand, experienced welders find a solution for a large number of cases from long practice in analogous work, and such men often possess a strong sense of anticipation in dealing with expansion and contraction effects and consequently prepare their work accordingly.

It is proposed to examine a number of common difficulties in welding operations brought about by expansion and contraction effects and to suggest methods of preparation and welding which will eliminate or correct these effects. There are many ways of taking care of expansion and contraction, but the four principal methods are as follows:

(1) Arrange the lines of welding and weld in such a manner that the effects of contraction are distributed and divided up so as to neutralize their effects.

(To be continued.)

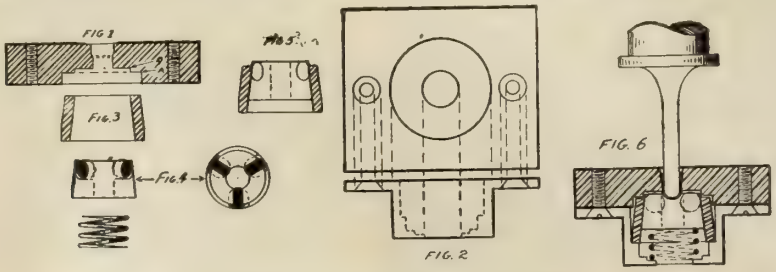
Practical Ideas for Shop Executives

STRIPPING SMALL SHELLS FROM PUNCH

By Chas. E. Hall



AN UNUSUAL form of stripper for drawn work, is shown in the accompanying drawings. In drawing brass shells for the well-known Bull Dog guards for tie pins, trouble was experienced by the shells remaining on the punch and coming back through the die, on the upward stroke of the press. As a dial feed was used, with the press running continuously, this was a decided inconvenience, as sometimes two, or even three would be forced through the die on top of each other before the operator could stop the machine.

Besides slowing up production, there was great danger of damage to the tools; consequently a stripper of positive action had to be devised. The superintendent decided to use the principle of the Bull Dog guard itself, using three steel balls instead of two as in the guard. A new drawing die was made and the back turned out as shown at Fig. 1. A cold rolled steel holder, the size of the die, and ¾ in. deep was turned down and bored out to contain the working parts as shown at Fig. 2. A hardened steel sleeve, Fig. 3, slightly tapered inside and out and 9/16 in. high, was made to fit freely in the recess A, Fig. 1. Next a cold-rolled cage containing three ¼ in. steel balls was made with a taper to conform to the inside taper of the sleeve. This was 7/16 in. high and projected through the top of the sleeve about 1/16 in., Fig. 5, and fitted freely in the recess B, Fig. 1. The steps shown in the section of holder, Fig. 2, were for the bottoms of the sleeve, cage, and spring respectively and shown in the assembled drawing, Fig. 6. The holder was screwed to the back of the die as shown at Fig. 6 only two balls are shown as it more clearly illustrates the action of the stripper.

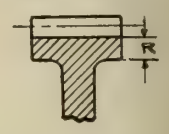
When the punch descends with a drawn shell on it, there is no resistance except that of the spiral spring which is depressed; but on the up-stroke of the press, the balls grip the shell at the top edge on one side, and the tapered wall of the hardened sleeve on the other, and holds the shell rigidly while the punch is being withdrawn, and when out, the shell drops through. The balls make slight marks, but as they come near the edge of the shell, the trimming removes them.

In marking a stripper of this kind, care must be taken to see that when the cage is up to the limit on the up-stroke of the press, that the space between the balls and the punch is just sufficient to grip the shell, but not enough to leave any chance of seizing the punch, Fig 6, where the solid black on the end of the punch represents the shell being drawn.

This stripper has proved very positive in its action, and can doubtless be applied to advantage where similar trouble has been experienced.

Stripping small shells from punch.

STANDARDS OF RIM THICKNESS FOR GEARS



By Robert Mawson

One of the bothersome jobs for the draftsman when designing gears is to know how thick to make the rim under the tooth so that it will be strong enough and yet not be heavy in section. Most gear designs now only show the outside diameter of the gear and perhaps a dotted line to represent the pitch line of the part, it being considered a waste of time to show the tooth outline on the design. Under these conditions it is rather difficult for the man on the board to visualize when the correct rim has been called for as the true shape of the gear is not shown. Of course the designer might draw out one of the teeth and show the rim and thus obtain the proportions, but this is time spent which could be used perhaps to better advantage, at any rate in many drawing offices this procedure is objected to by the chief.

With this in mind we recently compiled the table shown in the illustration and it has proved not only a time saver but also ensures gear designs uniform in their nature and yet strong enough for service. The first column gives the pitch of the tooth, the diametral system being expressed, but of course this can be easily converted to the circular pitch for shops using the latter system and then the nearest figure for the pitch given would be used. The second column expresses the proper thickness for the desired rim for any pitch in question, for example when designing a 7 diametrical pitch gear the thickness of the metal under the tooth would be ¼ inch.

Knowing this factor the draftsman has only to take the total depth of the tooth, which can be obtained from any text book dealing with gears, and adding these two quantities together he has

PITCH	R
2	1
2½	29/32
3	19/32
3½	1/2
4	7/16
5	3/8
6	5/16
7	1/4
8	3/16
9	3/16
10	5/32
12	5/32
16	1/8

FORMULA

$R = \frac{1.769}{P}$

P = DIA. PITCH

Gear rim data.

the thickness of metal from the outside of the gear to the under side of the tooth where the rim meets the arms or web. I have also incorporated in the table the formula as shown so that if the draftsman finds it necessary or advisable to add other pitches of gears he may easily do so by using the given formula. As an example, taking an 18 diametrical pitch gear and desirous to obtain the dimension R, divide 1.769 by 18, and .098 is the result and as 3/32 of an inch is .0938 this would be considered close enough and would be used as the thickness of the rim under the tooth.

EFFICIENCY

By I. N. B.

What is efficiency? The Romans invented the word, it means getting the most out of things. In almost any shop may be found instances where improvement can be effected by a little study of the conditions. Take the twist drill, one of the most common tools used in machine shops. And it is safe to say there is no class of cutting tool used that receives so little consideration as the twist drill. Most every tool room has a box of broken drills, tangs twisted off, split down the center, etc., and it is generally accepted that the cause is unavoidable. It is largely due to the fact that the drill can be bought ready for use. As a result the mechanic is likely to assume that the manufacturer has produced a tool ready for use, but which is capable of remaining in good condition with very little attention.

As a matter of fact the proper grinding of a twist drill is of the utmost importance, and unless the drill is ground

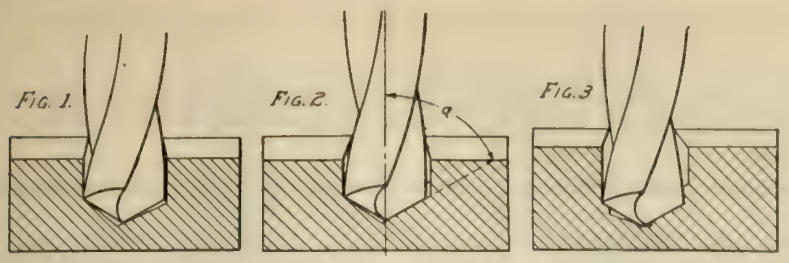


Fig. 1.—Lips of different inclination. Fig. 2.—Lips of different length. Fig. 3.—Lips of different length and inclination.

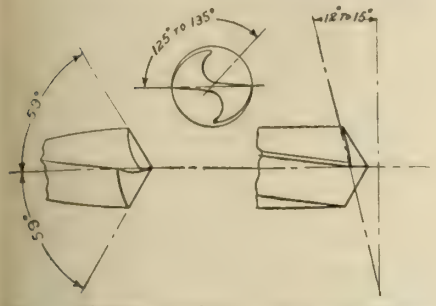

Fig. 4.—Showing angle of rake and clearance.

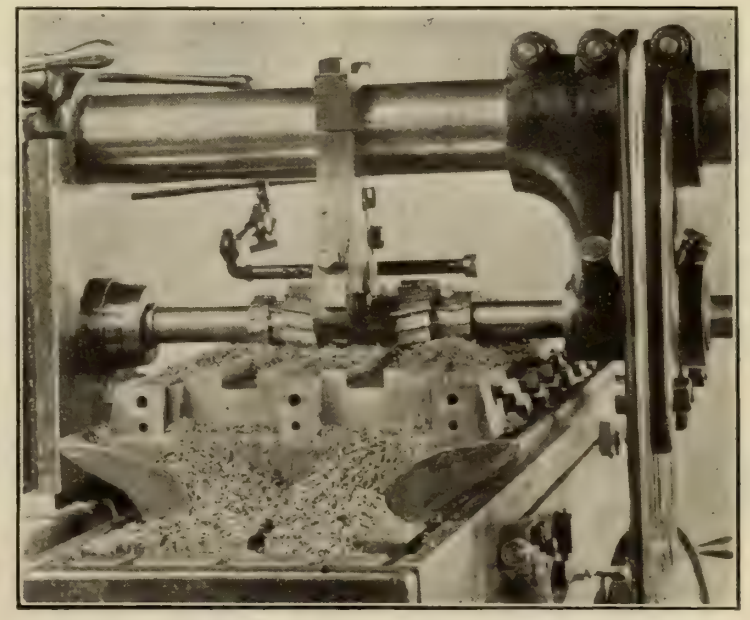
to the proper shape its cutting efficiency is seriously impaired, notwithstanding that the drill manufacturers have furnished the information how to grind drills to get the best results. Different manufacturers have made a series of tests that prove if the proper precautions are taken in grinding and the feed used as specified the results as claimed will be maintained. Improper grinding not only causes unnecessary breakage but produces spoiled work, which adds to the cost of production. To cite one instance: The drill operator had a lot of pump cylinders to drill for studs. The drawing specified the right size of drill to use for the tap drill. He received the right size from the tool room but in grinding he got one lip longer than the other, the result was that the drill cut over size, so that when they came to be tapped there was only stock enough for less than a half of thread. It became necessary to redrill and use a larger stud and re-drill the cylinder covers.

The only sure way to prevent the occurrence is to grind the drills on special drill grinders which are so designed that they assure the producing drill points that must be of the same angle with the center of the drill, both cutting lips must be of the same length. The drill point must have the proper lip clearance and this clearance must be the same for each side of the drill. All of these factors are imperative if satisfactory results are to be obtained. In the accompanying sketch, Fig. 1 shows action of drill with the lips of different inclination, Fig. 2 shows lips of different length, Fig. 3 shows lips of different inclination and different lengths, Fig. 4 shows angle of drill point, clearance, and angle made by chisel point with the cutting edges of drill. While it is possible to grind drills by hand it is not the most efficient method, where much drilling is done the drill grinding machine will give good returns on the investment.

SPEED CHANGING BY WORM GEARING

By Nick Andrew



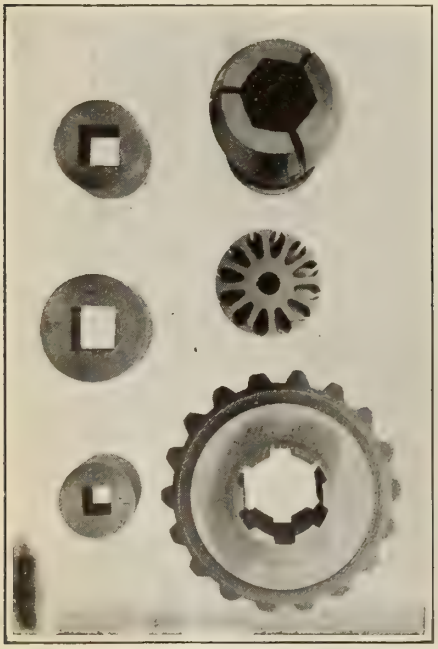
James Watt was a strong advocate of the worm gear, but owing to the difficulty of making this gear in efficient form it was not very largely used during the 19th century. Of late years, however, engineering practice has advanced so much that it is possible to make worm gears of the highest quality at a moderate price. Many engineers have therefore reverted to the principles laid down by the famous inventor, and we find worm gears recommended and used for vehicle driving and other purposes where they were once regarded as hopelessly inefficient. In view of the interest recently taken in worm gear, it is really remarkable that the first patent for the use of the worm gear for speed reduction and speed changing has just been taken out. A British inventor has obtained patents all over the world for this application. In his device the usual spur wheels are entirely absent, and nothing but worm wheels are used. In his speed reduction gear, the first shaft carries a worm which drives a worm wheel on a second shaft at right angles to the first. This second shaft in turn carries a worm driving another worm wheel on a shaft at right angles to the second shaft. This third shaft in turn carries a worm wheel on a shaft at right angles to it, the final effect being that the fourth shaft is in line with the first shaft and is driven by it at a speed reduced three times. This type of gear has been applied already to the driving of a mechanical stoker and to motor car accessories. In the case of the mechanical stoker the reduction is in the extraordinary ratio of over 27,000 to one—a result which could not possibly be obtained by means of ordinary gearing unless it were made of preposterous dimensions. In the case of motor car speed changing gear several ratios can be obtained with remarkable simplicity. The distinguishing feature of the gear is its small size in relation to the high reductions it provides. The inventor claims that the gear has an efficiency between 80% and 90% where the reduction is less than 250 to 1.

GANG MILLING OPERATIONS

By H. James

The accompanying illustration shows an interesting operation being performed on a Herbert horizontal milling machine. As can be seen from the cut a special roller steady bracket is employed as an added support to the cutter arbor. This steady is firmly secured to the overhead arm and the roll holders are adjustable. A finger extends down from the front of the bracket and contained in this rod is a small pin with a felt insert for brushing chips and dirt from the arbor so that a clear path is presented to the rollers. The material operated on is steel bars of from 35 to 40 tons tensile strength. In the gang of cutters two are operating on the side and two on the face, the latter being 5½ in. in dia. The spindle speed is 25 r. p. m. and the feed one in. per minute.

Sliding parts of machine tools should be well lubricated—not over lubricated. Oil on a part not subjected to friction may do more harm than good.



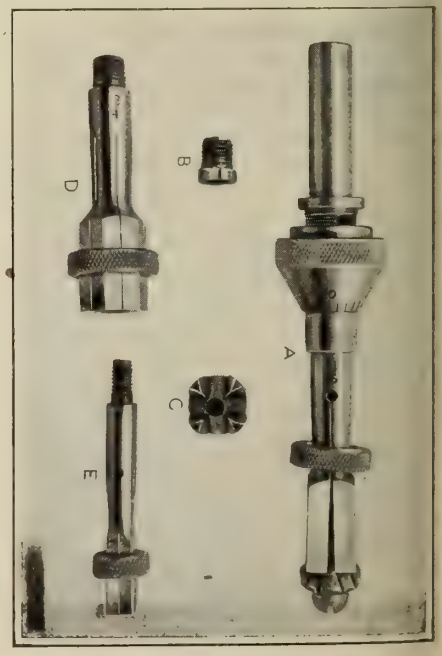
Steady support for milling machine arbor.

New Things in Shop Equipment

STAYBOLT THREADING MACHINE

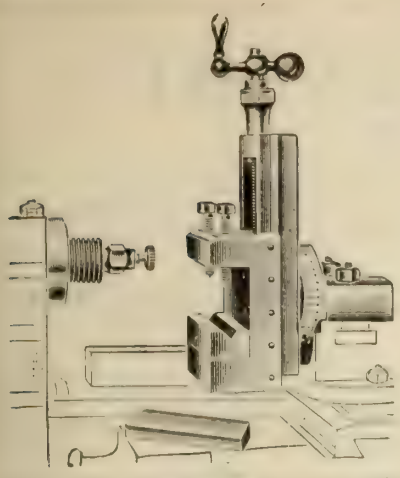
There has appeared on the market recently a machine intended for threading staybolts in railroad shops. The machine is really one of the standard turret lathes that the firm manufactures, but instead of the turret on the carriage there is located the staybolt threading attachment. When not required for staybolt threading, the attachment may be replaced by the regular equipment. The machine is capable of cutting any size of thread on crown, button-head, and swivel staybolts up to 40in. in length. Self opening die-heads are supplied to meet the particular requirements of the shop in which the machine is installed. In an operation on upset button, head forgings, which were taper-formed under the head and on which a thread was cut both under the head and on the opposite end the production rate was one staybolt per minute. The attachment has two cam-operated die heads on the carriage of the machine. The rough forging is passed through the forward die-head into the square collet of the automatic chuck, located in the spindle of the machine. The die-head has an enlarged hole in the shank, and the chasers open exceptionally wide to enable the staybolt to be chucked in this manner. After the staybolt has been chucked, the staybolt carriage is fed forward until the extended end of the bolt is supported in the steady-rest between the two die-heads. The head end is then formed by a cutter on the cross-slide, after which the staybolt carriage is again fed forward during which time the die-heads being operated by cams at the rear, close automatically and cut the threads. When the die-heads have passed the cams the dieheads again open. The carriage is then returned to the back end of the machine. As the action of the heads is dependent on the contour of the cams, the latter are made to suit the job. The threads on both ends of the staybolt are cut in a continuous lead, the thread on the extended end being cut without any previous machining. The machine and attachment are manufactured by the Warner and Swasey Co. of Cleveland, Ohio. The machine on which the attachment is mounted is the regular No. 4 turret lathe made by this firm.

Showing various parts produced by broaches.



ADJUSTABLE BROACHES

A line of tools that can be used for the broaching of square and hexagonal holes, splines, keyways, and round grooves, in small lots, has been recently placed on the market. The broaches are adjustable. They are intended to be attached to the spindle of a drilling machine, the ram of a shaper or arbor press, the tool post of a lathe carriage, or other machine members suitable for traversing a tool without rotating it. The broaches are made in various styles, the square and hexagonal types being made regularly in all sizes from ¼ to ¾ in. across the flats. The broach is held in a holder that has a micrometer adjustment. Each broach is hollow, the front end being ground to the shape of the hole to be produced, and split. The rear end is threaded to screw into the holder. A rod extending through the hollow broach has a pilot screwed on the forward end after the broach has been assembled. This pilot is of the same diameter as the hole to be machined, and thus serves to keep the entire unit steady in an operation. The pilot is provided with ribs that engage the splits of the broach and keep the cutting edges free of the tool from swerving sideways. The pilot is also employed for adjusting the cutting edges. Prior to the first cut, the ribs of the pilot only slightly engage the splits of the broach. Then after the broach has been given one pass through the work, the pilot engages the splits to a greater amount thus expanding the broach. To thus engage the tapered ribs of the pilot in the splits of the broach, the knurled member of the holder is revolved the desired number of graduations. Each graduation represents .001in. Each broach is provided with a ring gauge to set the cutting edges properly for the first cut. An adjustment is required after each cut is taken. The tools are made by the Edward Hollander Tool Co., of Newark, N. J.



HIGH-SPEED PLANER

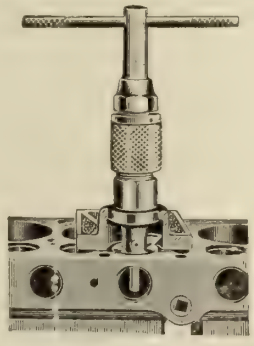
A special planer 26 x 32 x 18 in. intended for high-speed operating has recently been developed. The table operates at a speed of 150 f. p. m. on both the cutting and return strokes. A unique feature in the design is responsible for a very smooth running machine. The shaft, carrying the tight and loose pulleys, passes entirely through the bed, and carries on its other end a small pulley, which drives a larger pulley by a belt on which the tension is maintained by means of an idler. The power is then transmitted through a helical pinion and gear, which together with the belt drive just mentioned, are on the outside of the planer bed. On the helical gear shaft is mounted the pinion that engages the steel rack under the centre of the table. The bed of the machine is cast in one piece. The table contains three "T" slots, but no holes are provided. The steel rack extends the whole length of the table. Thirty inch driving pulleys are provided.

Two heads are mounted on the cross rail, and both of these heads operate on the one screw. The minimum distance between the tools is 12 in. The material, which the planer is designed to handle, consists of composition brass screen plates about 30 x 13 in. in size. The machine is manufactured by the Whitcomb-Blaisdell Machine Tool Co. of Worcester, Mass.

Details of adjustable broach.

Lathe milling attachment set up for cutting keyseats.

LATHE MILLING ATTACHMENT

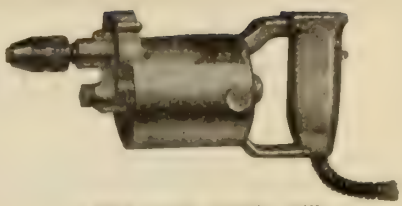


The attachment here illustrated has just been placed on the market. It is a handy device that can be used for light milling work on the lathe, squaring the ends of shafts and auto axles, sawing, splining shafts, and a variety of other small jobs. The attachment is secured to the top of the compound rest and in such a position that the centre of oscillation is at a low point, making it extremely rigid. Graduation is provided so that accurate angular setting is readily obtained. The device is manufactured by Hinckley Machine Works, Hinckley, Ill.

RACK-CUTTING AND INDEXING ATTACHMENTS

There has recently been placed on the market a rack-cutting and indexing attachment which is designed to operate on heavy duty milling machines. The rack cutting device is securely attached to the face of the column and is further supported by the overhanging arm at a point directly above the spindle where there is the greatest strain. The attachment is driven through a shank held in the machine spindle by means of a tang and a draw-back. A hardened spur gear keyed and pinned drives a second gear keyed to the same shaft on which a double lead worm is mounted. The latter engages a worm wheel which is located on a shaft that with two spur gears keyed to it, one on each side of the worm wheel. These transmit power to the attachment spindle through gears cut solid on this member. The spindle is made of alloy steel, and runs in bronze taper bearings that have means of adjustment for wear. The rack indexing attachment is fastened to the left-hand end of the table by means of the central T-slot. It consists of a bracket carrying an indexing and locking disc and change gears. This device permits of cutting rack teeth and making other settings without relying on the usual dial. Various gear combinations enable racks of different pitches to be indexed by making one half, one, or two turns of the locking disc. The cutting of racks to the following diametral pitches is possible by means of eighteen change gears furnished:—3 to 6 by half pitches, all pitches from 7 to 16, and all even pitches from 18 to 32. Racks having circular pitches of from 1/16in. to 1in. may also be cut. A special rack vise is provided having jaws 30in. long which have a maximum opening of 5⅝in. The attachment is manufactured by the Rockford Milling Machine Co., Rockford, Ill.

VALVE RE-SEATING AND BORING TOOL



A very important factor in the overhauling of motors and pumps is to see that the valves seat properly and to do this they must be in perfect alignment with the valve guides. A device for performing this has just been placed on the market. This appliance does not depend on the small pilot end to guide the cutter, but the latter is guided by a large accurately ground bearing above the valve seat. A screw feed is provided and the tool is held steadily to the work, and no digging in or chatter takes place. When refacing valve seats top and bevel are both faced so that a narrow and effective seat is always presented to the valve, thus aiding in expelling the carbon. Cutters are made of high speed steel and shop and garage men can resharpen and keep them in shape. The set consists of three boring bars, with 5/16in., ⅜in. and 7/16in. pilots; two valve seating cutters, 45 deg. angle; one knurled handle; two boring cutters and wrench. All incased in mahogany finished chest. Weight, 18 lbs. It is manufactured by the Hinckley Machine Works, Hinckley, Ill.

Valve reseating tool.

Valve reseating and boring set in mahogany case.

High speed electric drill.

SMALL ELECTRIC DRILL

A small but highly serviceable electric drill has just been offered to the trade. It is extremely compact and has remarkable strength for drilling ¼in. holes in steel. It weighs only four pounds and can be supplied with either 110 or 220 volts motor, suited for direct or alternating current. It is amply provided with oiling and ventilating facilities, and is fitted with bronze bushings and gears. The drill can be held and operated with one hand, and chuck and drill are always in view of operator. The Lovejoy Tool Works, Chicago, Ill., are the makers.

HIGH-DUTY DRILLING MACHINE

There has recently appeared on the market a redesigned heavy-duty drilling machine, where simplicity has been the keynote and aim of the designers. The machine has a capacity for drilling a 1-½ in. hole through solid steel. Nearly all the operating members are contained in the head, which is very accessible and lends itself to dismantling. The head is bolted to the vertical face of the heavy box section upright. When these bolts are removed the head can be taken away by means of a crane. The upright, base, and jackshaft support are cast integral to insure rigidity. All operating levers are located at the front of the head. The single screw of the table permits a 12 in. vertical movement of this member without providing a hole in the floor for the screw. The machine has a single pulley drive, and the power is applied through the medium of a friction clutch. Nine spindle speeds, ranging from 75 to 610 r. p. m. are provided. There are three feeds of .006, .012, and .026 in. per rev. and these are available through sliding change gears. Helical gears are used to transmit power from the pulley shaft to the spindle. The spindle feed consists of a double rack and two pinions in order that all side thrust be eliminated. Roller bearings are supplied in all driving shaft bearings and ball bearings take care of the spindle thrust. The speed change gears run in an oil bath while the feed gears are lubricated by a splash system. The upper driving helical gears and their bearings are packed in grease. One packing is usually sufficient for several months running. Some of the principal dimensions of the machine are —from centre of spindle to face of column, 10in.; maximum distance from nose of spindle to top of table, 28-⅝ in.; length of power feed, 12 in.; and the approximate weight of the machine is 2,700 pounds. The machine is manufactured by the Foot Burt Co of Cleveland, O.

Can We Simplify Machine Tools?

"SIMPLIFICATION is a program much more far reaching than most business men, I believe, yet realize," said Mr. Parsonage, general manager of the John Deere Wagon Works, not very long ago.

Secretary Hoover, who requires no further introduction, for we know the wonderful work he has accomplished for the United States, is also a firm believer in simplification. When addressing a brick makers conference recently he said, among many other things, that the simplification proposal they were making was not a new idea, but was exceedingly worth while because in this case it was inspired by the manufacturers themselves.

These two prominent men do not believe in simplification as a theory, but practise it themselves. Mr. Parsonage admits there was a time when manufacturers of implements made practically every variation in style that buyers felt they wanted. What they wanted was usually determined by what they had previously been accustomed to. To show how simplification pays, here is what one implement dealer experienced. In 1913 he listed fourteen sizes of implements, carrying not more than three of each kind. After simplification, his last order called for only four sizes, with not less than five of each kind, and his assortment of implements was equally complete.

The brick makers in their conference, decided that the manufacturers ordering fire brick would not lose any efficiency in their furnaces, were the makers to simplify and reduce the sixty-six varieties then manufactured. The result is almost beyond belief. After careful investigation it was found that the manufacturer could be equally well served with eleven varieties in place of sixty-six. Not only that, but the brick maker could produce at a lower cost, and sell to the consumer at a proportionately lower figure.

What can be done in these two lines, and many others which we could mention, can be accomplished in machine tool circles. There is no need for so many varieties. The difference in some cases is very slight, and simply a talking point. If machine tool manufacturers would get together, allow their designing staffs to collaborate, a standard style of drill, lathe or miller as the case might be, could be designed which would embody all necessary features, yet reduce machining costs to a minimum.

Various sizes of such tools would have to be made in order to accommodate different classes of work, but not the enormous mixture now on the market. An objection which would likely be raised to this suggestion is "Why should a large manufacturer give a small producer of inferior grade tools the benefit of his experience?" This is not intended, for when we say "Get together" we mean only the recognized tool builders. Certain patented features might be adhered to, but even at this point it might be well to waive claims on the idea, giving designers a free hand, when a better and improved design might result. This suggestion is very idealistic, and would take a long time before it would become an established fact, but nevertheless there are great possibilities in it, if tackled in the proper spirit, viz., one of striving after simplification.

Both the manufacturer and consumer would eventually get the benefit. Those concerns who are almost making a tailor built tool would have to give way to simplified modern manufacturing methods. There will, of course, always be certain groups which must continue, such as engine lathes, automatic lathes, continuous millers, etc., but each of these lines can be simplified in order to lower the cost to both the consumer and the manufacturer.

Protecting the Worker

AT OTTAWA the other day a resolution was moved, urging that in addition to the accident insurance now available, parallel protection should be afforded to all workmen contracting sickness while performing, or due to the performance of their work or trade. Later on the motion was withdrawn because of the principle that workmen's compensation acts were within the sphere of provincial legislation. In other words, each province had a right to arrange matters for themselves.

At present the term accident does not, according to law, include sickness or desease, even though the latter may be the direct result of some work performed daily. Take for example the making of matches. It is known that in many cases constant work in this industry has resulted in the loss of eyesight and contraction of tuberculosis and that although several notable improvements in working conditions have taken place, a danger from a health standpoint still exists.

Match factories are not the only traps in which health can be impaired, because we have pickling rooms, tanneries, bronzing rooms, chemical factories of some kinds, foundries, etc., all of which in some form or other eat away the vitality of the worker. To look at some of the present day molders will perhaps make one doubt that the industry is unhealthy, but examine their lungs, and see what you discover.

How far we could safely go in the awarding of sick benefits could not be arrived at in a day, but through careful research by competent medical men, the industries could be arranged in groups according to their health hazard.

When a workman devotes his energies to some unhealthy trade he deserves compensation when his useful period is over. It would be a splendid forward step were the different compensation boards to take this matter up with the manufacturers, thus adding still another link to the chain of welfare work, existing between the employer and employee. Such investigation might lead to the removal of the danger, which would be the best form of protection.

ON ANOTHER page of this issue appears a short comment on an article and editorial we published on April 27. We are glad to note the subject has caused comment and we feel that many other manufacturers could to advantage express their views.

Iron and Steel Market Continues Firm Tone

Increase in Business Reported by Steel Merchants—Galvanized Sheets Advance—Small Tools and Supplies Active—Machine Tools Holding Their Own—Non-Ferrous and Scrap Metals Quiet —Pig Iron Demand Tapers Off

INCREASE IN PRICE OF GALVANIZED SHEETS

CANADIAN markets generally are firm. Demand is keeping up as well as can be expected, and with a few exceptions, there is no cause for complaint. The iron and steel section is showing decided signs of strength, and the volume of business closed so far this month indicates that it is by far the best this year. Dealers were looking for improvement in May, and in the majority of cases, the volume of added business is satisfying them. Galvanized sheets are particularly active, and the price is now $5.60 in place of $5.35.

Roofers are exceptionally busy, and in some cases cannot accept further orders. A well-known Canadian representative of a large American concern, states that if Canadian consumers do not place orders for their steel requirements in the near future, they will be sadly disappointed in delivery dates, for the American steel mills are booking a large number of orders ahead. Railroad material is in heavy demand in the States, but Canadian markets will not show strength in this respect until the government decides to spend money on track material. Such a move is unlikely at present.

Non-ferrous and scrap metals are very quiet. Pig iron has also tapered off. Consumers of pig seem to be pretty well covered, and until the rate of melt is increased in foundries throughout Canada, no added interest can be expected.

Small tools and supplies continue to be in fairly good demand. Enquiries are general, this applying both to goods and locality. Machine tools are holding their own, but large orders are not being closed. Single machines are usually asked for but several good prospects are, according to dealers, nearing the closing point. The general tone of this section has improved and dealers are not discouraged, although the volume of business actually closed is small.

Steel pipe is very firm, and deliveries are becoming more extended all the time. Oils, waste and greases are in good demand. Oils dropped slightly in price over the week, but nothing to speak of, but it shows that the tendency is downward, not upward. To prove that some things can go up, gasoline took a jump of 1½ cents per gallon during the week, but whether the rumor of a still further advance will take place is very questionable.

Conditions in the steel market in the United States show still further improvement. The April report of the American Iron and Steel Institute places the production rate of steel ingots during last month at about 35,500,000 gross tons per year. This is ahead of March, the average rate for that month being 32,500,000 tons.

A few sources predict that steel production will fall off around July, but from present indications this does not seem feasible, because several steel companies have large orders booked ahead, and are in some cases accepting rush business at premium prices. In the short period of three months, the steel market has changed from a buyers' to a sellers' market, and from information received, the source of which we cannot divulge, the steel companies themselves are confident the present strength will continue.

Some firms are finding it difficult to secure coal, owing to the strike, and are moving this commodity unusual distances in order to meet the situation. No relief is expected for some months to come.

Connellsville coke presents a very narrow market, both offerings and enquiry being extremely light. Foundry coke is also quiet. Connellsville coal has advanced slightly, eastern buyers having entered this market. Steam grade is selling from $3.25 to $3.50 per ton.

Pig iron shows high prices but few purchasers. One or two forced purchases brought a price of $25 valley, an advance of $1 over a week ago, and an actual market of $18 April 1. Bessemer is quoted at $26 valley. Foundry remains at $23 valley, but consumers are staying out of the market as long as they can owing to these high prices.

Toronto

May 17,

CONDITIONS locally remain steady. The steel market is particularly firm, and an advance in price has been made in galvanized sheets.

Iron and Steel.—Bars, shapes, and sheets are active the latter being strongest of all. The building trade is responsible for the activity in galvanized sheets this material being used for metallic roofing, eavestroughs, etc. The price has now advanced to $5.60 for 28 gauge and this quotation is being held to quite firmly. From present indications, May business will show a decided advance over April, and in the majority of cases, dealers are satisfied with the volume of business showing. A local representative of a large American steel company states that spikes, angles, and other railroad material is in heavy demand in the United States. He claims that his company is booking a large amount of orders ahead, and that delivery is getting to be an important factor. To show this is a fact, several important letters were read to the writer, everyone of them bearing out the statement that the mills confidently expected the strength and demand to continue. According to our informant, several Canadian consumers are hanging back, thinking all this talk of demand is propaganda, but as he puts it "the result will be that they will be unable to secure material except on delayed delivery.

The rumor persists that iron and steel bars may go up in price, but at present the quotation is still the same. Until competition in these lines diminishes, it is unlikely that an advance will be made. Quotations follow:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Non-Ferrous Metals.—This is a weak market, the demand being practically negligible. Prices remain the same, and following are the present quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals.—This is another quiet market. Until foundries show more activity, we cannot expect much improvement. Following are the quotations:

Copper, light, per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Medium brass	4 50
Yellow brass turnings	4 75
Light brass	3 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	16 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	6 00

Pig Iron.—This market has tapered off somewhat during the last two or three weeks. When the recent advance in price was rumored, everybody rushed for cover with the result that the market is now rather stagnant. The rate of melting in foundries does not seem to have increased lately, so that stocks of pig must be rather high in

some foundries. It is unlikely that there will be much improvement in this market for another month at least. The present quotation of $29.15 still holds firm in spite of small demand.

Machine Tools.—The smaller sizes of tools are selling at a fair rate, but the demand is not very brisk in the heavier machines. No large orders have been closed, mostly single tools being asked for. More interest is being taken in the market, however, and several good prospects are on tap. Dealers are not downhearted but feel the improvement, while rather slow, will be steady.

Small Tools and Supplies.—This section of the market shows good signs of strength. May business will be ahead of April if the present demand continues. One large dealer handling many lines reports exceptionally good business and he is taking some men off slow moving lines, such as agricultural machinery, in order to get all there is going in other fields. The sections particularly active in his case are, pumps, taps, reamers, etc., plumbers' supplies, hand tools of all kinds, and other miscellaneous supply lines.

Oils and Greases.—The demand for oils and greases remains good. Prices in oils have dropped slightly. The new quotations being as follows:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	0 33
Black oil, per gal.	0 17½
Cylinder oil, Capital	0 61½
Petroleum fuel oil, bbls., net	10 40
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00
Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bls. gal.	1 35
Linseed oil, raw, single bls.	1 10

Miscellaneous.—Waste is selling at a steady rate, and the demand for leather belting is fairly good. Steel pipe is very firm, deliveries being more distant. Prices are steady, and the mills, not the buyer, now do the dictating.

WASTE

Montreal

May 17

TRADING in iron and steel on the local market has been about the same during the week as for some time past. The same lines that were active last week continue to move freely. This is particularly true of all building supplies. In common with this demand there is a fair amount of business being done in structural steel. No large orders have been booked, but there is a quantity of small orders, which run into a fairly good tonnage.

Steel prices have not undergone any change during the week, but there still remains a fairly stiff tendency on all quotations. Sheets, particularly British galvanized sheets, are in excellent demand. Pig iron and non-ferrous metals are quiet. Machine tools are being aggressively pushed and sales are slowly responding. Machine shops report that a little more business is in evidence and that conditions are improving.

Iron and Steel.—For some weeks past, reports would indicate that quotations on steel products were to undergo an upward revision. This belief still persists, but the base price of $2.75 remains unaltered. Even this base price is shaded for attractive orders, so that while these facts seem ambiguous and contradictory, they nevertheless exist. The coal strike is the explanation. If the strike is of long duration, prices will naturally advance. On the other hand should a settlement be effected it is questionable if an advance would be made. Buying has been stimulated by this uncertainty, also the strong stiffening tendencies in the United States before the strike materialized.

Merchant bars are moving satisfactorily. Orders are for the most part small, but they come from all parts of the country. Jobbing shops are receiving more business and are coming into the market. The demand for structural steel still continues in small lots. Galvanized and blue annealed sheets are moving in good quantities. The mills in the United States have been falling down in their deliveries locally, the result being that firms handling British sheets have been enjoying a greatly increased demand. One jobber stated that he was not only sold out, but that he had sold two consignments which were at present in transit from England. Plates, however, are very dull.

The railway companies are not placing any rail orders so again the mills are disappointed in this respect. Local quotations are as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Machine Tools and Shop Supplies.—Sales in machine tools have slightly increased, but only in small and single tools. Wood-working tools are still moving in a small way and dealers are disappointed in the way the market has responded to their intensive sales campaigns. General metal working tools are in fair demand only, while the supply business is improving as local shops are getting more business. There are no marked features other than the fact that the turnover was larger in most cases than last week.

Pig Iron.—Buying still continues quiet, although a fair number of single car orders were received during the week. No changes in prices have been announced. No. 1 pig is quoted at $31.80 per ton. There is an undercurrent of firmness to all quotations and is reflected in the ruling that no iron will be sold for delivery later than thirty days. Volume of production is diminishing in the United States as many furnaces are commencing to feel the shortage of coke.

Non-Ferrous Metals.—Everything continues quiet in the non-ferrous metal field. There are no price changes, and the small volume of business passing does not appear to be increasing. The stiffening in price in foreign markets was followed by a slight local increase, but this factor made no impression on the demand locally. The present prices are:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 00
Lead	6 75
Spelter	7 50
Antimony	6 50
Aluminum	23 50

Scrap Metals.—The demand for scrap in the United States, does not appear to materially increase the demand locally, although it did have the effect of sending up the price to a point that was sufficiently high to turn away any business that might be offering. The following list contains the local quotations, but business passing is taken at a somewhat lower scale, which is regulated entirely on the special transaction that is being made:

Copper, light per 100 lbs.	9 50
Copper, crucible	12 50
Copper, heavy	12 50
Copper wire	12 50
No. 1 composition	9 50
New brass cuttings	7 00
Red brass turnings	8 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	12 50
Boiler plate, per gross ton	8 50
Heavy melting steel	10 00
Axles (wrought iron)	9 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	22 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	18 00
Cast boring	3 00

Pittsburg

May 17

ON ACCOUNT of the possible effect of the coal strike upon the steel industry, the April report of the American Iron and Steel Institute, giving the output of steel ingots by the 30 companies that make monthly returns, was awaited with unusual interest. From the report it may now be computed that in April the production by the whole industry was at the rate of about 35,500,000 gross tons of ingots a year. March showed an average rate of 32,500,000 tons, the rate probably being about 30,000,000 tons at the beginning and 35,000,000 tons at the end of the month.

Thus, on the whole, production has increased since the coal strike began, even though the previous rate was a very high one, considering the general industrial and commercial situation, and that production in 1921 was only about 19,500,000 tons.

In the last analysis, however, the low production in 1921 is probably the best explanation of the high rate now. Buyers were liquidating stocks in 1921, while of late they have been replenishing stocks. It is hardly to be supposed that they are accumulating abnormally high or speculative stocks, but merely replenishing stocks, or bringing them up to normal working level. Even this would require quite a lot of steel. Production of steel decreased a trifle in certain districts in April, this being made up, with a margin to spare, by heavier production elsewhere.

The probability is that the rate has run between 36,000,000 and 37,000,000 tons a year right along since April 1. The present prospect is that production will increase somewhat in the next few weeks, although it usually falls off somewhat in July and August. Whether this year will furnish an exception remains to be seen.

Making Steel.—It is not easy for some of the companies to make steel just now, for with some of the usual sources of supply shut off by the strike, coal has to be moved unusual distances in some cases, and stocks are being drawn upon freely.

Precise figures are not available, but from various estimates and reports a rough picture of the coal situation may be given, which is sufficiently close to furnish a clear idea. In round figures there is bituminous coal producing capacity in the United States of 16,000,000 net tons a week, of which 10,000,000 tons is union and 6,000,000 tons non-union. Production has never been at full capacity throughout the country even for a single week, between 12,000,000 and 13,000,000 tons being a high rate. Consumption is between 7,000,000 and 8,000,000 tons a week at present and production, all non-union, is a trifle above 4,000,000 tons, leaving 2,000,000 tons idle non-union capacity, of which say half is idle on account of no market, and the other half is idle through strikes, brought about by the United Mine Workers.

Stocks April 1 were estimated at 63,000,000 tons, and consumption of stock is at between 3,000,000 and 4,000,000 tons a week. Part of the idle capacity that is not on strike is in small high cost mines which will operate in an emergency, and the major part is in districts remote from the heavy consumption. Such coal is being bought now, to be moved unusual distances.

The regular coal strike is likely to last for several months, while the strikes in non-union districts, instead of playing out in a few weeks as was at first expected, may last nearly, if not quite as long. The operators are making no effort to force the situation, preferring to get coal where they can, and at whatever expense is involved, letting the strikers wear themselves out.

Steel Market.—This section is very strong throughout. The actual turnover is not as heavy as in March or April, but mills are well sold up, at the present rate of production, for the next couple of months, and consumers in turn are well covered, there being some demand now for early deliveries, with buyers not entirely unwilling to pay delivery premiums. Quite a few buyers are offering mills third and even fourth quarter contracts, and when the mills have no regular quotations for those deliveries, buyers in some cases are willing to take the contracts and let the price be set later by the mills. In other words, the market has turned wholly in favor of sellers, whereas until quite recently it was a buyers' market, and it is hardly three months ago that the lowest prices were being made, there having been slight advances since then.

There are divergent views as to how long the present strength of the steel situation will last. Some expect a strong market throughout the year and even into the new year. Others think that much of the present strength depends on the coal strike, and that in the course of a very few months the strength will wear off. These observers do not think actual consumption is as heavy as current production.

Bars, shapes and plates remain quotable at 1.50c as the basis of the market, but the Steel Corporation is almost alone in quoting this price, and even the Steel Corporation makes it only on the most desirable business. In sheets, regular prices are 2.40c for blue annealed, 3.15c for black, 4.15c for galvanized and 4.50c for automobile sheets. At least half a dozen independent mills are quoting $5 to $7 a ton higher, but whether they will get much business at these prices remains to be seen. Steel pipe is very firm at 71 per cent. basing discount. Nails are still quoted at $2.40 by the Steel Corporation, and $2.50 by the independents. Tin plate is $4.75, but some of the independents have been thinking about advancing their prices.

Connellsville coke presents a very narrow market, offerings being light as well as inquiry. Furnace coke is quotable at $6.50 and only occasionally will a buyer pay this price. Foundry coke is $6.75 for standard grade, with occasional buyers. Connellsville coal has advanced, chiefly on account of the appearance on the market recently of eastern buyers, and is quotable at $3.25 to $3.50 for steam grade.

One or two forced purchases of basic pig iron have brought out a price of $25, valley, against a nominal quotation a week ago of $24, and an actual market April 1 of $18. Bessemer, by relation, is quoted at $26, valley. Foundry remains at $23, valley, with occasional transactions. In general, consumers will stay out of the market as long as they possibly can on account of the high prices.

CONDITIONS SHOW STEADY IMPROVEMENT

ACCORDING to reports from London, England, trade and industrial conditions in Great Britain are slowly but steadily improving. No big revival has materialized, but there has been a continuous betterment of conditions, a seemingly healthy growth, that has satisfied traders more than any sudden revival. An outstanding indication of the trend of affairs is that money is easier and more is being loaned, which indicates confidence in the trade situation generally.

Encouraging reports come from various trades, including coal, textile and pig-iron. General living conditions have improved, commodities haping dropped in price, and there has been a decrease in unemployment, although it is still large.

The Manchester Chamber of Commerce says that the hopes of a moderate revival of trade with India have been realized and that inquiries from India and China have been numerous. Egypt also has placed a fair number of orders. South America continues quiet. India, for many years the great market for British cotton goods, has become herself a manufacturer of such goods.

China has become more or less a manufacturing country, absorbing about 100,000 bales of American cotton last year. South America, notably Argentina and Brazil, have begun to manufacture textiles and generally all countries give signs of interest in domestic manufacture. While this shifting of production from one place to another creates certain difficulties, on the other hand, far from indicating depression it suggests the reverse condition.

Trade figures between Great Britain and the United States show some significant facts. For the three months ending March 31, 1922, declared exports from London to the United States aggregated £7,870,399, plus merchandise valued at $1,272,589, which was invoiced in American currency only, as against exports for the same period in 1921 amounting to £7,201,675.

If we remember how prices have dropped since a year ago, concludes the chamber, we shall see at once that not only has there been an increase in values, but a still greater increase in quantities. The large single items of these exports which show increases are: leather, precious metals, gums, linens, scrap metals, aluminum, linseed oil and copper concentrates.

An essential in die grinding is that the dies in a set be ground uniformly.

The Page Steel and Wire Co., of Bridgeport, Conn., have just issued a new handbook describing and illustrating developments in the welding industry. The book is full of instructive information on the production of iron and steel, and Page-Arinco welding rods and electrodes.

News From the Industrial Field

The Union Iron and Metal Co., Toronto, have made an assignment for the benefit of their creditors.

The Longhead Machinery Co., Sarnia, are making industrial trucks, and report good business.

The Coca Cola Co., 65 Bellwoods Ave., Toronto, are considering the erection of a manufacturing plant. George A. Porter is Toronto manager of this concern.

The Toronto Motor Car Co., 52 Jarvis St., Toronto, will soon erect a garage, warehouse office and service station on Adelaide St.

The Thorton Blanket and Woolen Co. Dundas, Ont., will erect a factory costing $18,000. Major E. H. Greenwood, has been awarded the general contract.

The Thomas Knitting Co., Bowmanville, Ont., will proceed with the erection of a factory costing $100,000. H. L. Quinn has been awarded the general contract.

Windsor, Ont.—Stores and apartments costing $12,000 will soon be erected for A. L. Hamilton, 482 Church St., Nicholas, Sheppard and Colthurst, architects, in the Dowler building are preparing the plans.

The Superior Wrench and Tool Co., of Toronto are just completing an order for $1,200 worth of wrenches which will be shipped to an English purchaser before the close of the month.

A foundry building costing $50,000 will be erected for Hillis and Sons, Halifax, N. S. The Nova Scotia Construction Co., Halifax, and Lockwood, Green and Co., of Canada, Montreal, have been awarded the contracts.

Effective at once, Mr. K. O. Shepard, is appointed Roadmaster of the Newport and Orford subdivisions, in place of Mr. L. Hebert, reports the Canadian Pacific Railway, office of the superintendent.

Fort William, Ont.—The northern Engineering Co., were unfortunate enough to experience a fire on May 9, the stores and workshop sections comprising the newest wing of plant being destroyed. The loss will be about $25,000.

According to Frans de Boer of Heemstede, Holland, his country may soon have a building at the Canadian National Exhibition, Toronto. Mr. de Boer, who is at present visiting Toronto, says that Dutch merchants have been discussing closer trade relations with Canada.

The P. Lyall and Sons Construction Co., Montreal, have just closed a contract for $250,000 worth of marble work and other improvements to the Windsor hotel of that city. Another contract for about the same amount of work is expected in the near future.

Tenders for the masonry, brick and the Ottawa civic hospital will be received up to 2 p. m., 30th May, by the chairman of the board of trustees, city hall, Ottawa. Tenders must be submitted upon forms furnished by the architects. An accepted check for 2 per cent. of the bulk tender price, together with a bid bond, must accompany each tender.

F. J. Macdonell.

Hamilton, Ont.—F. J. Macdonell, who for the past three years has been branch manager here of the Victor Saw Works and Clemson Bros., Inc., and has been for seven years associated with that firm has resigned to accept the Canadian management for Millers Falls Co. of Millers Falls, Mass., and will cover Canada personally for a time in the interests of the latter firm.

A local report states that a Canadian National freight train of 102 cars, claimed to be the largest on record, arrived in Winnipeg from the West on May 11th. This train, of which 96 cars were loaded with wheat, was drawn by a single engine, and made fast time. The wheat was destined for the head of the lakes. The length of the train was approximately 4,000 feet and the tonnage was in excess of 5,000 tons.

London:—The prospects of a trade revival in great Britain were discussed by two prominent business authorities the other day, and here is how they summed up the situation. Reginald McKenna, banker, said movements in bank advances marked the earliest stage of a trade revival. Manufacturers are now requiring more money to finance their operations. Their turnover is more rapid, more trade bills are coming for discount and there is a greater demand for bank acceptances to finance foreign trade. All these movements which bankers are now experiencing, pointed to increased activity. Stanley Baldwin, president of the Board of Trade, gave a similarly hopeful survey in the House of Commons. He said Britain was slowly climbing out of the appalling pit into which she fell at the collapse of the war boom.

The Hamilton Cotton Co., Hamilton, Ont., are having an addition made to their present factories. These improvements will cost $20,000. Stuart and Sinclair, 17 Jackson St., E., have secured general contract. The Hamilton Bridge Works, Hamilton, A. B. Ormsby Co., Toronto, and John E. Ruddel and Son, Hamilton, have received contracts for steel lintels, sash, roofing, etc.

"Increased advertising by Canadian manufacturers in Canadian publications is absolutely essential to make a 'made in Canada' movement a success," remarked Russell T. Kelly at a meeting of the Toronto Advertising Club a few days ago. Mr. Kelly pointed out that 60 per cent. of the advertising in Canadian magazines at present is American, so that a large slice of business was therefore getting away from Canadian business houses.

H. N. Cowan, of the Cowan Co., Toronto, has been elected president of the Confectionery, Biscuit and Chocolate industry in Canada. E. D. Littler, Montreal, has been made first vice-president; F. McCormack, London, Ont., second vice-president: Colin Currie, Toronto, treasurer and C. J. Bodley, Toronto, secretary. The executive committee consists of: C. Monahan, Halifax; J. S. Pluard, Joliette, Morden Neilson, F. O'Connor, C. E. Edmonds, W. Robertson, Toronto; F. W. Bean, Woodstock; C. C. Wardrobe, Winnipeg, and D. S. McFarlane, London.

The automotive industry is experiencing great activity at the present time. Experts in close touch with the situation predict that May will set new high production records, and Percy Owen, president of the Liberty Motor Co., says that he believes good business is going to extend over the balance of the year, principally for the reason that people are feeling better. "It is unlikely that the tremendous spurt now on will be continued," says Mr. Owen, "for buying of motor cars has come back with a rush after a long continued void. We must recognize, however, that the buying today is the buying following an almost total cessation over a period of months and for that reason is not normal."

Save from One-Third to One-Half on Machinery

That is what you save when you secure a Williams Remanufactured machine. Moreover, we guarantee all machines re-manufactured by us to be equal to new for all practical purposes. No matter what piece of machinery you want, we either have it, or can get it for you at an advantageous price, and you can buy from Williams with full confidence that you will get bigger value for your money than you can from another house.

If you are interested in receiving our monthly Machinery list, write us and we will put your name on our mailing list.

64 Front Street W., Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

At the annual meeting of the Canadian Railway Club in Montreal a few days ago, a very successful business and social session was held. The retiring president, Mr. Arthur Crumpton, turned over the reins of authority to the newly elected president, Mr. G. M. Wilson, superintendent of motive power shops, Grand Trunk Railway System, Montreal. The other officers elected were: first vice-president, H. R. Taylor, assistant manager, Angus Shops, Canadian Pacific Railway; second vice-president, C. E. Brooks, mechanical superintendent, Canadian National Railways, Toronto; executive committee, E. R. Battley, superintendent of motive power, G. T. R., eastern lines, Montreal; J. A. Shaw, general electrical engineer, Canadian Pacific Railway Company, Montreal; W. U. Appleton, mechanical superintendent, Canadian National Railways, Moncton, N. B.; R. J. Needham, mechanical and electrical engineer, G. T. R., Montreal; John Burns, workshop manager, Angus Shops, Montreal; W. C. Hunter, air brake inspection, Canadian National Railways, Moncton, N. B.; Auditors, C. F. Needham, assistant to general superintendent, motive power and car departments, G. T. R., Montreal; J. W. Fontaine, chief clerk to the department of stores and mechanical accounts, C. P. R., Montreal; J. D. Brandon, representing the American Arch Company, Montreal. Secretary W. A. Booth, engineer locomotive construction, G. T. R,. Montreal. Treasurer, P. P. Reynolds, chief clerk to chief of motive power and rolling stock, C. P. R., Montreal. The retiring president, Mr. Crumpton, was presented with a jewelled emblem as souvenir of his term of office on behalf of the executive and membership generally, the presentation being made by Wm. M. Macnab, chairman of the valuation committee of the G. T. R., and one of the past presidents of the club.

CONTINUE GOOD WORK

THE National Screw Thread Commission has had its term extended to March 21, 1927, and during that time, will go into the standardization possibilities of the subjects mentioned below:—

Sheet metal and wire gage numbers; tap-drill sizes; bolt, nut, and rivet proportions; bolt-head, nut and screw-head standardization; standardization of instrument threads and those cut on brass-tubing; standardization of acme, square and other special threads, a study of tolerances and stock sizes for cut and rolled threads, etc.

Arrangements have been made for co-operation between the National Screw Thread Commission and the sectional committee of the American Engineering Standards Committee which is studying bolt, nut and rivet proportions. The sub-committee which will work with the American Engineering Standards sectional committee on the matters pertaining to bolts, nuts, rivets and screw-heads, is composed of F. O. Wells, E. H. Ehrman, and Commander J. N. Ferguson. A sub-committee consisting of Dr. Stratton, Commander Ferguson and Mr. Wells will make a tentative study of the standardization of instrument threads and brass tubing threads. Another sub-committee composed of Major J. O. Johnson, R. E. Flanders, Lieut.-Commander C. A. Jones and Earl Buckingham will take up a study on acme, square and other special threads.

At the meeting held in Washington recently a report on tap drill sizes was submitted, and with certain changes this will be submitted to the industries interested for comment and criticism before any final action is taken to make the new suggestions a national standard.

In connection with the study being made of sheet metal and wire sizes, Col. E. C. Peck submitted a decimal system in accordance with the proposal made by the American Society of Mechanical Engineers in 1895. At that time the mechanical engineers recommended the discarding of all gage numbers with the idea that wire and sheet metal could be described better by decimal parts of an inch—the number of thousandths of an inch indicating the gage number as well as the exact size.

The Shredded Wheat Co., Niagara Falls, Ont., will erect two storage buildings at a cost of $152,000.

The town council of Hanna, Alta., are considering the purchase of an electric lighting plant.

F. S. Mallory, 165 Bay St., Toronto, is preparing plans for a garage to cost $50,000.

Prince Rupert, B. C., may be the site of a new grain elevator. The proposed structure will cost $500,000.

The board of education, Whitby, Ont., is contemplating remodelling their school at a cost of $15,000.

Toronto, Ont.—Tenders for the installation of one four million imperial gallon centrifugal pump at the Island pumping station will be received up to June 13.

Windsor, Ont.—The Haymon Construction Co., of London, will erect freight sheds for the C. P. R. at an approximate cost of $200,000.

A service station and plant costing in the neighborhood of $18,000 will be erected by the Imperial Oil Co., 56 Church St., Toronto in the near future.

Electric mine lamps are being installed in the collieries in Cape Breton, replacing the old "Glanny" lamps, which are oil burners.

A station will be erected at Sarnia, Ont., for the Pere Marquette Rlys., the cost of which will be approximately $40,000.

The Shawinigan Water and Power Co., Shawinngan Falls, Que., have had plans prepared for electric lighting system to cost $10,000.

The York Sandstone Brick Co., East Toronto, are in the market for flat topped steel cars for use in sand and lime brick manufacture.

C. W. James, Jnr., 95 King St. E., Toronto has been awarded general contract for erection of apartment house to cost $50,000 on Neville Park Blvd. He is now calling for tenders from all trades.

Toronto, Ont.—A recommendation to spend $6,000 to rebuild one of the furnaces at the western incinerator, pending the construction of a modern garbage destructor has been made by street commissioner Wilson.

During the month of April the Scotia collieries produced 53,163 tons, with Princess leading with 21,615 tons—534 tons ahead of Florence, which came next in the running.

Sault Ste. Marie.—Permits totalling over $50,000 have been issued in this city since the first of May. At present the demand for permits is exceptionally great.

London Ont.—A concrete bridge costing $25.000 will be erected on the North River Road for the G. T. R. Chas. Forester, Supt. is interested, and plans for both the steel and concrete work have already been prepared.

W. G. Murray, Dominion Savings Bldg., London, has plans for the erection of a school at Brownsville, Ont., which will cost around $10,000. Tenders are being asked for and no closing date is set so far.

The Standard Oil Co., of New York, have advanced the price of gasoline one cent a gallon in all its territory. A similar advance has been made in the price of varnish makers' and painters' naptha.

Dr. J. W. Ross, trade commissioner in Shanghai, will arrive in Canada some time in August next. He will make a tour of the towns and cities in which exporters are located who are interested in the trade of China.

The Sydney Mines, N. S., school board has appointed a committee to call for plans for a new school building at a cost of about $75,000. The Bank of Nova Scotia is to erect a one and a half story bank agency building at Sydney Mines, work to commence about June 1st.

Dundas, Ont.—The Canada Crushed Stone Corporation intend reconstructing the portion of their plant recently destroyed by fire as soon as possible. Mr. Buckbee of Chicago, the company's consulting engineer is at present looking after this work.

Pembroke, Ont.—Sealed tenders will be received up to the first of June by Findley Watt, for the supplying of all materials and the construction of a dam near Waltham, Que. The dam has to be completed according to plans and specifications prepared by J. L. Morris, Pembroke.

A. W. Swan, assistant secretary of the Engineering Institute of Canada, Montreal has resigned and sailed for England. He intends to reside there permanently, and while in this country was associated with the Canadian Ingersoll, Rand Co., Sherbrooke, Que., before branching into editorial work for the Institute.

Major G. B. Johnson, trade commissioner in Glasgow, will arrive in Canada about August next and will tour those towns and cities which contain exporters interested in the trade of either Scotland or Ireland. Major Johnston is at present making a tour through Ireland.

Halifax, N. S.—Work has started on the new foundry building for Hillis and Son of this city by the contractors, the Nova Scotia Construction Co. The building will be of concrete and brick, and of fire proof construction throughout. The plans are by Lockwood, Greene and Co., Montreal.

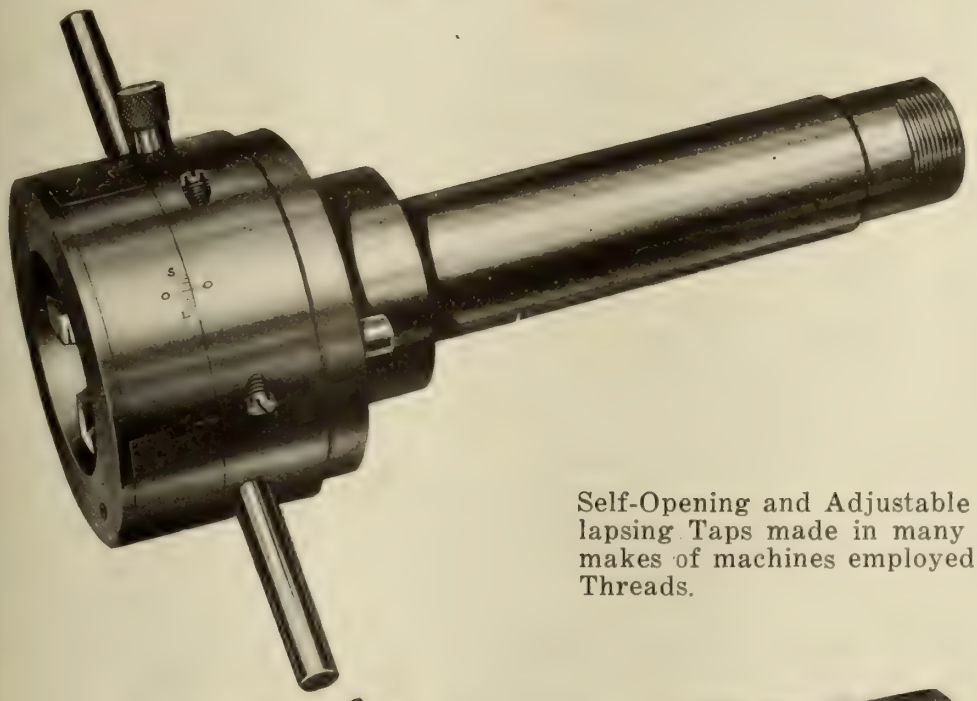
The general contract for the erection of Riverdale Technical School has been awarded to Witchall and Son, 156 St. Helens Ave., Toronto. This is valued at $577,370, and the additional contracts are, W. G. Edge, Ltd., ventilating, plumbing and heating $112,000, Canadian General Electric Co., electrical $24,700, and Ryrie Bros., time clocks valued at $1,870.

Sydney, N. S. W.—Before trade with Germany reopens on August 1st precaution will be taken to guard against the dumping of goods here at the expense of British and Australian manufacturers. A tariff board has been appointed to impose penalties in any case where its members are satisfied that local industry is likely to suffer.

Acceptance of a new street lighting contract for Sydney, N. S., drawn up by the Cape Breton Electric Co., and recommended by the street lighting committee, has been decided upon by the aldermen of the council, though they were not unanimous. The matter of urging the federal government to proceed with construction of the Sydney terminal wharf is to be considered by the council.

A recent 80 ton test of quartz from the Brookfield Gold mine at Brookfield, N. S., proved a yield of $13.45 gold per ton, while $10 per ton was recovered by crude stamp mill methods. A cyanide process is soon to be installed. The company operating the Mine at Brookfield the King, Fissure Mines, Ltd., have purchased the surface property of the Switzer Mining Co., at Fifteen Mile, and are removing the machinery and material to their own property, and will add ten stamps and an air compressor. Since the test they have started to sink another hundred feet to open up more ore.

The Canadian Engineering Standards Association, Ottawa, Ont., have made the following changes in the personnel renominations of members of the main committee. Sir Alexander Bertram, replacing Mr. Tye. Mr. C. W. Lafebvre, replacing Mr. A. Surveyor. Dr. L. A. Hardt, renominated. Dr. R. A. Ross, renominated. Prof. P. Gillespie, renominated. Mr. T. E. Sutherland, renominated. Mr. A. R. Goldie, renominated and Mr W. A. Bowden having been nominated as a member of the main committee by the department of railways and canals, replacing Colonel Monsarrat, it was decided to co-opt Colonel Monsarrat as a member so as to retain his services on the committee.



The Purchasing Agents' Association of Toronto, have sent about 30 members to Rochester to the annual convention of the National Association of Purchasing Agents, which is being held from May 15th to 20th. Keen interest is shown in the national elections, as one of the Toronto members, Major J. R. Bell, of Business Systems, has been nominated for vice-president. The promotion of standards will be one topic to which the National Association will give considerable discussion. The standardization committee of the national body has been at work on standard forms of various kinds for the last two years, and as a result of their efforts the Bureau of Standards of the Department of Commerce at Washington has obtained the co-operation of producers in reducing the number of styles and sizes of many commodities.

C. M. A. ELECT OFFICERS FOR YEAR

During the recent Toronto meeting of the Canadian Manufacturers' Association, a resolution was passed which states that the association is in favor of a system of preferential tariff within the Empire, similar to the preference now contained in the customs tariff of Canada, but as the Canadian tariff is already a generous one, they do not favor any further lowering of the British preference at the present time, on account of the damage it would do to Canadian industry, and they felt it would be unfair to Canadian firms to ask for further preference, in view of the fact that the British preference is slight, compared with the Canadian preference to Britain.

The meeting also went on record as favoring the lowering of freight rates, to the same extent that farmers and others have reduced their operating costs.

Following are the officers elected:—Chairman, Ontario division, Col. Arthur F. Hatch, Hamilton; vice-chairman, George Brigden, Toronto. Toronto branch, chairman, R. H. Easson, re-elected; vice-chairman, Melville F. White.

Ontario division.—Members of the division executive council: James Arnold, Brockville; Henry Betram, Dundas; John M. Campbell, Kingston; E. J. Davis, Newmarket; Geo. D. Forbes, Hespeler; W. C. Franz, Saulte Ste. Marie; W. M. Gar shore, London; W. T. Goodison, Sarnia; Lloyd Harris, Brantford; Fred Hatch, Whitby; F. S. Hodgins, Kitchener; E. H. Jones, St. Catharines; R. W. Leonard, St. Catharines; R. O. McCulloch, Galt; G. W. McLaughlin, Oshawa; E. D. Smith, Winona; W. C. Springer, Belleville; R. Thompson, Carleton Place; C. H. Waterous, Brantford; D. M. Wright, Stratford.

Ontario division, members of the division executive committee.—W. R. Breyfogle, Peterboro; George Brigden, Toronto; G. C. Cockshutt, Brantford; H. W. Fleury, Aurora; Fred Hatch, Whitby; T. A. Hollinrake, Toronto; J. G. Hossack, Toronto; William Inglis, Toronto; C. B. Lowndes, Toronto; B. J. McCormick, Welland; C. H. McGhie, St. Catharines; J. F. McKay, Ingersoll; W. H. Marsh, Hamilton; F. E. Mutton, Toronto; J. D. Payne, Welland; H. D. Scully; W. H. Shapley, Toronto; John Taylor, Guelph; H. J. Waddie, Hamilton; C. R. H. Warnock, Galt.

Toronto branch executive council.—L. L. Anthes, E. M. Ashworth, Thomas Bradshaw, George Brigden, C. H. Carlisle, F. S. Corrigan, W. C. Coulter, Gordon C. Crean, E. J. Freyseng, E. Holt Gurney. R. Harmer, Sam Harris, T. A. Hollinrake, William Inglis, W. C. Laidlaw, C. B. Lowndes, J. S. McLean, T. F. Monypenny, W H. Shapeley, J. O. Thorn, G. W. Watts.

Even the best excuse for being late is not half so good as being on time.

Annual Meeting of Quebec and Montreal Division, C. M. A.

THE annual meeting of the Quebec Division and the Montreal Branch of the Canadian Manufacturers' Association was held in the Windsor Hotel, Montreal on May 11th. Advance in every line of work was shown in the reports submitted. About one hundred delegates were present, representing the Quebec Three Rivers, Sherbrooke and other branches of the Association, as well as the local branch.

The reports showed that general business had more than doubled during the year, and that all sections had increased their membership and activities. After addresses from the retiring chairmen, the main business was the reception of reports and the election of officers. The result of the election of officers was as follows:

Montreal Executive

Chairman, Julian C. Smith; vice-chairman, A. O. Dawson; committee, W. S. Atwood, Howard Bird, Archibald Baillie, Kenneth Dawes, H. T. Diplock, W. A. Eden, W. S. Fallis, R. H. Gillean, W. R. Granger, D. E. Hamilton, John Lowe, W. H. Miner, N. C. Poison, Jr., Alph. Racine, Lyon Cohen.

Representatives on executive council, Jos. Beaubien, Jos. Daoust, R. M. Davy, Art. Harries, Geo. Henderson, M. Hirsch, F. H. Hopkins, A. D. Huff, T. P. Howard, John Irwin, R. H. McMaster, A. Neighorn, S. F. Rutherford, Paul Sise, N. M. Yuile, F. R. Whittall.

Quebec Division

Chairman, F. W. Stewart; vice-chairman, Paul E. Joubert; committee, E. C. Budge, Leslie Drake, A. S. Ginger, Raoul Grothe, Michael Hirsch, Norman Holland, F. W. Knowlton, A. McA. Murphy, Walter, Ramsay, A. Edgar Robertson, Robert Ryan, Albert Tetreault.

In his annual report, the sec'y, R. W. Gould, said that many unexpected changes had occurred during the year, the volume of business having more than doubled in twelve months, in order to meet the growing demands of the members. Two and a half years ago the division had a staff of a secretary and stenographer. Now they have a secretary and some fifteen employees engaged in the different departments. The large number of circulars, notices of meetings, letters, and election campaign work was referred to. The activity of the branch in the Made-in-Canada campaign was reviewed. It was further mentioned that all circulars sent out from the head office at Toronto had been sent out from the Montreal office, but in this case the circular had also to be prepared and sent out in French.

The important feature of the year was the inauguration of a transportation bureau in charge of G. P. Ruickbie which had been made use of continually by the manufacturers throughout the province. A number of other trade organizations had also joined with the C. M. A., working with it, thus increasing its membership and volume of business. In spite of the fact that this was a period of trade depression the work of the branch has grown steadily. It appeared that all British and American firms desiring trade information had seen fit to make use of the services of the C. M. A.

Mr. F. G. Daniels of the Quebec division reported a net gain in membership from that quarter in spite of the fact that the trade depression has been the cause of several resignations. The recently established Export Club of Montreal had been a great assistance to the Association and helped to increase membership. W. R. Grainger presented the report of the municipal affairs committee outlining its activities in connection with the governmental system of Montreal, and the movement to secure the building of another bridge from Montreal to the South Shore.

B. W. Coughlin, the retiring chairman, pointed out the difficulties under which the manufacturers had been operating during the past year, everyone having felt the pinch of changing conditions. During the year the depth of depression had been reached and he felt confident that now there is a stable move in the right and upward direction. Manufacturers during the year had learned a sharp lesson and should capitalize it. Many firms, wholesale, manufacturing and retail, had taken their losses and readjusted themselves on a new basis, which showed a healthy condition of business. This movement had been retarded by the fact that business conditions in Canada were dependent on those in other countries, many of which were much more disturbed than the Dominion. Caution and thrift had been the watchword among manufacturers during the past year and he urged that the same safe and sane policy be practised during the coming twelve months. The meetings closed with votes of thanks to the retiring presidents and other officers.

The St. Lawrence Hotel Building Port Hope, was lately sold and is at present being remodelled into an up-to-date knitting plant. The company which has bought the building and will operate the plant will be known as the Amalgamated Knitters, being composed of several knitting companies. The building is large enough to combine all the plants into one, and should be one of the finest knitting works in Canada. The Port Hope business is developing rapidly and although only in its infancy, has grown to be known from coast to coast as producers of fine grade knit goods.

Avoid the use of metal hooks or wire laces in belts that have to be shifted by hand as there is always a possible chance of injury.

THE
TORONTO IRON WORKS
LIMITED

HEAD OFFICE: ROYAL BANK BLDG. TORONTO WORKS: CHERRY STREET

The Perfect Grip

An ordinary hammer will slice the head off a nail, because it gets a grip on the head and not on the nail. With the head off, it's all off.

Williams' perfectly balanced Hammers will grip the **body** of a nail and pull it, head and all, clear through a plank. All nails are trailers to Williams' hammers.

Heads on or heads off, for drive or pull, Williams' Superior Drop-Forged Hammers are the bosses in the nail world. Good workmen want them because they fit the hand, are perfectly balanced and are good all through.

Literature?

J. H. WILLIAMS & CO., Limited

"The Drop-Forging People"

30 Thorold Rd., St. Catharines, Ontario

Gray Iron Castings Ground Fast, Clean and at Low Costs

In removing gates, fins, seams, etc:

1. What is your production per hour?
2. What is your production per grinding wheel?
3. What is the life of your grinding wheel?

Can the figures from your answers to these three questions be improved upon?

Try

Norton Crystolon Vitrified Grinding Wheels

and let the figures answer for themselves

There's only one correct grinding wheel for a job. Using the wrong wheel entails expense which should be eliminated.

Every Railway Engineer

Should Read
The Important Series of

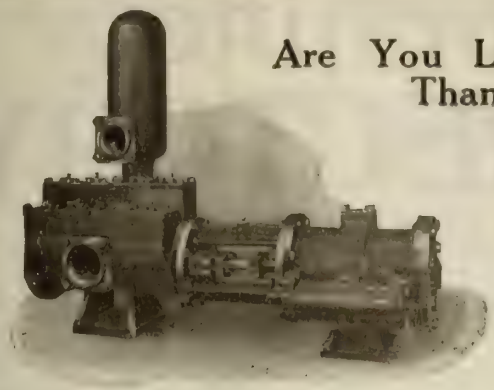
LOCOMOTIVE and RAILWAY ENGINEERING NUMBERS

of

Engineering Production

The British Journal of Works Practice and Administration

MARCH 16th to MAY 4th Inclusive.



These numbers deal fully with the production methods employed in the great British railway works, and all modern plant and equipment as applied to the requirements of the railroad is described and illustrated.

Details are given of the best practice in the railroad and independent locomotive shops of this country, also of works systems, every phase of the latest works methods being dealt with.

"Engineering Production" is Published Weekly, price 6d., and may be obtained through any newsagent or bookstall, or direct from the publishers, price 7½d. a copy, post free.

Subscription Rates: Great Britain, 32/6; Canada, 32/6; Other Countries Abroad, 36/10 per annum, post free.

Publishers: ILIFFE & SONS, LTD.,
Dorset House, Tudor St., London, E. C. 4.

Are You Looking for a Steam Pump that's Better Than the Ordinary? Then take Note of this

HEPBURN

In the Hepburn Steam Pump the steam chest is located on the side of the cylinder and the low ports automatically drain away all condensation. This prevents water hammer in the cylinder and ensures a perfect cushion for the steam piston. The Hepburn is the only self-draining Pump made in Canada. There are no levers or tappets to get out of order. You will find our prices right.

We also make: Vertical Engines, Compressors, Winches, Cut Gears, Derricks, Brick Machinery, Hydrants, Blacksmith Work and Grey Iron Castings.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

For Difficult Drives,

such as cone drives in Paper Mills, in places exposed to cold and wet, or hot and dry conditions, this superior, efficient belting invariably makes good. We cite the instance of difficult drives because it is in the extreme tests that

"P.M.S" Belting

has especially excelled. "P.M.S" Belting will not slip or stretch, and withstands conditions of heat and dryness, or cold and wet. Made from the toughest of Sea Island Cotton, and rubber-friction-surfaced "P.M.S" offers a tremendously strong belting. It is made in convenient lengths and widths to suit any drives.

Don't Take Our Word For

GUTTA PERCHA & RUBBER, LIMITED
TRADE P.M.S MARK
TORONTO, CANADA

"P.M.S" BELTING

Try it! Test it! Compare it!

We court investigation. "P.M.S" Belting is recommended, and sold strictly on its merits—of course; it's well-made of exceptional materials. The toughest of Sea Island Cotton, rubber-friction-surfaced to make it non-slip and assure the maximum transmission of power, is the basis of "P.M.S" excellence. But, to convince yourself, just try it! Test it! Compare it with others! Give it the severest trial you like, so long as it's a fair one. Then, you'll appreciate "P.M.S", as we know it—practically perfect belting.

Peak Profits With the Landis

There will be thousands of new automobiles, trucks and tractors purchased this spring, and every one of them represents a future business prospect for the repair shop man.
There are added thousands of vehicles, now registered, that will require repairs before starting on the new season's runs These represent **immediate** prospects.

Are you going to go after some of this present business and gain a reputation that will assure your future? You can do so by installing a

LANDIS

No. 5 Cylinder Grinding Machine

This machine possesses a number of distinct advantages that make it unexcelled for cylinder regrinding. Its range covers every type of auto cylinder bloc.
The Landis Centering Fixture permits of speedy and accurate location of cylinder bores with spindle and thus reduces set-up time.
Let us tell you why the Landis is the choice.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

Keep Production At Top Speed

Efficient production demands elimination of lost time. By making your gasoline supply easily accessible, at every needed point, Bowser Piston-Type Measuring Pumps save workmen's steps and time.

The long-distance pump delivers gasoline where it is to be used and measures it in the exact amount required, without spillage or waste.

The patented Bowser centrifugal separator assures clean, power-full gasoline, free from all moisture and sediment. The double cog rack assures easy operation.

Bowser equipment provides large underground facilities, enabling you to buy gasoline at quantity prices, eliminating the fire hazard and assuring minimum insurance rates.

To save money and speed up production, write for illustrated Booklet C-13.

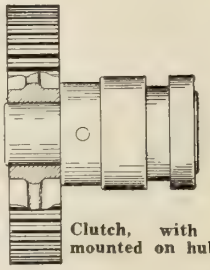
ACCURATE MEASURING PUMPS

THE JOHNSON FRICTION CLUTCH

IS USED ON THE

PEERLESS DOUGH MIXER



Courtesy of the Peerless Bread Machine Co., Sydney, O.

A No. 4 single clutch is used to facilitate starting and stopping.

Lubrication is a necessity for all running bearings and frictions and an occasional application is all that is necessary.

Adjustment of the Johnson friction clutch is simple. A small screw moves two taper blocks in toggle levers, giving greater expansion to ring — thus more gripping power.

Clutch, with gear mounted on hub.

The Johnson friction clutch is a small, compact and very powerful device for machinery of all kinds where medium or light power is transmitted.

THE DICTIONARY OF APPLIED PHYSICS

Five Volumes Fully Illustrated

edited by Sir Richard Glazebrook, K.C.B., D.Sc., F.R.S.

VOL. I.—MECHANICS—ENGINEERING AND HEAT
VOL. II.—ELECTRICITY.
VOL. III.—METEOROLOGY, METROLOGY, AND MEASURING APPARATUS.
VOL. IV.—OPTICS, SOUND, AND RADIOLOGY.
VOL. V.—METALLURGY AND AERONAUTICS.

It is our privilege to announce the most comprehensive and important work on its subject yet published. A Dictionary of Applied Physics in five volumes.

The first attempt which has been made to bring within the compass of a single work the latest results of research, and the most approved methods in all branches of Applied Physics.

A unique work of reference, containing a mine of information invaluable, not only to those engaged in professional work, but also to manufacturers, who are concerned with the question of Physics as applied to Industry.

Applied Physics is a comprehensive subject and the task of gathering the applications has been difficult. The dictionary will appear in five volumes of 800 to 1,000 pages each, and the Editor has secured contributions from the most competent authorities in Great Britain and America.

The volumes have been arranged as far as possible in subjects. The arrangement in each volume is alphabetical, but each main subject is dealt with in a continuous article, reference being given, each in its alphabetical position to the headings of the various sections of an article and the subject it includes.

You will no doubt be keenly interested in this valuable and unique work, which has long been needed by Industry and Science, and we would like to send you further particulars. If you will sign the attached coupon, this additional information will be sent. It does not obligate you in any way whatever.

VOL. XXVII. No. 21. MAY 25, 1922.

Saving Money By Means of the Turret Lathe

Production Increased by Efficient Chucks and Work-Holding Fixtures—Indexing Devices With Ample Wearing Surface Most Suitable—Machining Hydraulic Shock Absorber—Operations on Bronze Valve

By H. ALTON

ONE of the most interesting machines in the ever widening range of machine tools, is the turret lathe. All the interesting features of an engine lathe are present and in addition, there is a broader field of application. that is limited only by the ingenuity of the tool designer and engineer. There is always a certain amount of time consumed in setting up a job, chucking it, and in otherwise handling it, in and out of a machine. If these chuckings and handlings can be reduced. there is obviously a large saving in time. The ratio of time consumed in chucking and handling, to time taken in performing a single operation, varies according to the design of the work-holding fixtures, the nature of the machining, and the shape of the piece. It is not unusual to run across a job where it requires as much time to chuck the piece of work, as it takes to accomplish the machining operation. Another argument in favor of the fewer number of chuckings, is that of accuracy. It is impossible to set a piece of work a second time and obtain results that are absolutely concentric with the portion machined in the first setting. A limit of a few thousandths of an inch, or more, must be permitted.

Information and cuts 1 to 4 by courtesy of Millholland Machine Co., of Indianapolis. Data and cuts 5 to 10 through courtesy of Jones & Lamson Co., of Springfield, Vt.

For these reasons it will be seen that it is most desirable, from a point of view of economy, and also of accuracy, to reduce the number of chuckings. To accomplish this on a lathe, there was developed the turret, which carried several tools and was able therefore to perform with one setting, multiple and complex operations. For a number of years turret lathes have been improved and an infinite number of fixtures have been applied to them.

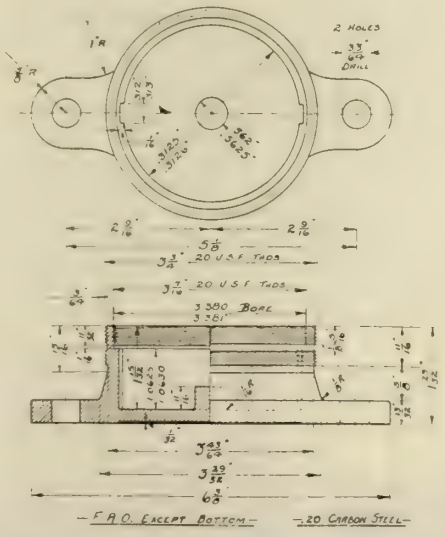

Fig. 1.—Hydraulic shock absorber machined on a turret lathe.

Chucks and Work-holding Fixtures

One of the important matters to consider in connection with the turret lathe is the work-holding fixture, or chuck. If the work is circular and of a symmetrical concentric design, a good universal three-jaw type of chuck can be used to advantage. It is more than likely that special jaws will be required, with faces machined to locate successive pieces of work in a definite position relative to the turret and other component parts of the machine and the tooling. The nature of the machining operation has to be considered and provision made to grasp the work in such a manner that it will not be dislodged, if for any reason an excessive pressure of the tool is placed upon the work. Then again the chucking problem has to be considered from another angle. A piece should be held so that the greatest possible number of machining sub-operations can be done without re-chucking.

In some lines of work a type of collet or draw-in chuck is found to give good results. In this type of chuck special provision has to be made to ensure that the pieces of work of slightly varying diameters are gripped in the same relative position with regard to the turret tools, cross slide, etc. In a

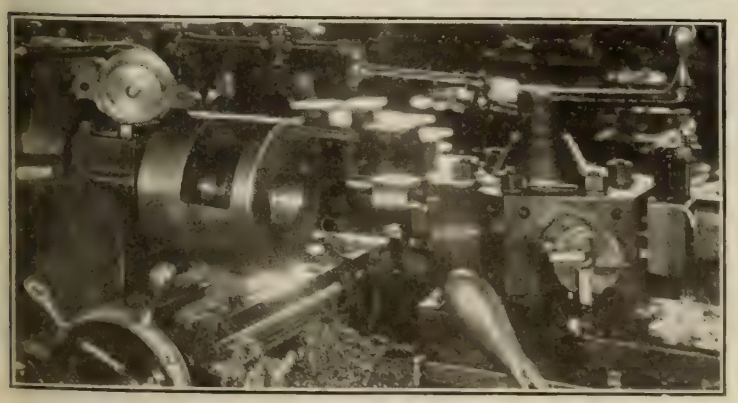

Fig. 2.—Turret lathe tooled to machine hydraulic shock absorber shown in Fig. 1.

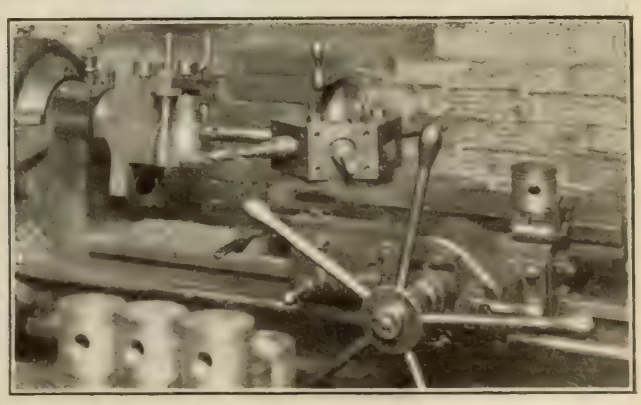

Fig. 4.—Cross boring gas engine pistons on a turret lathe.

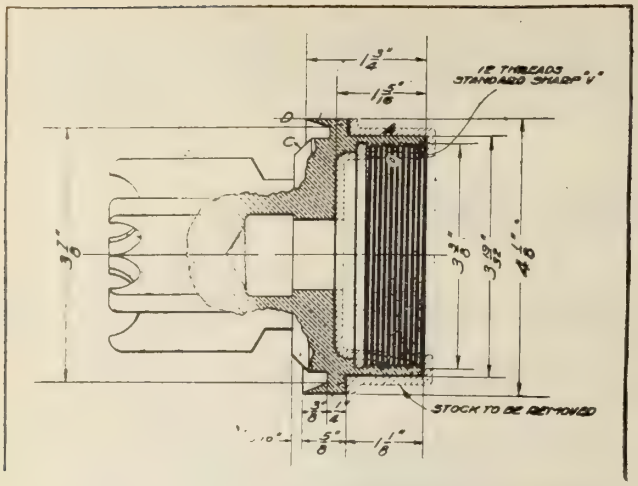

Fig. 5.—Outline of bronze valve showing metal to be removed in first operation.

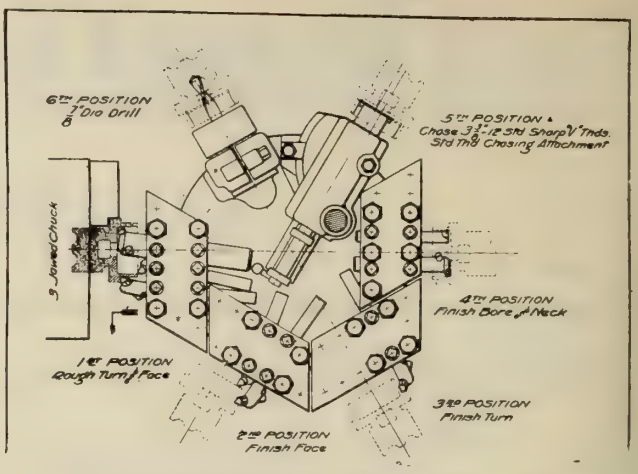

Fig. 7.—Tooling layout for first operation on bronze valve.

great many instances longitudinal cuts are governed by stops which have a fixed position on the lathe bed. Thus if the piece of work were chucked a few thousandths of an inch farther in or out than the previous piece, the longitudinal dimensions of the latter would be in error to just that extent. Instead of designing the chuck to overcome this difficulty some engineers operate their stops by making contact with the work. This is not a good practice as the revolving work causes undue wear on the stop and renders it necessary to adjust it continually. For finish operations this practice is useless. It may be permitted in roughing operations only, but even then it is not desirable.

The methods of applying chucks to turret lathes do not present the same difficulties as are encountered in work-holding fixtures. Often an irregularly shaped piece comes to a turret lath that has had some previous operations performed on it, and it has to be located according to the machined surfaces, and grasped in such a manner that there will be no interference with further operations it is desired to perform. The design of these work-holding fixtures is a very extensive subject, and would provide material for many articles. The general principle followed is, to have a definite finished part, or unfinished portion of the work, register against a certain finished part of the fixture, in such a way as to locate it relative to the tooling. The fixture is further designed to drive the work in a positive manner. A single strap, or hinged portion of the fixture is usually the only moving part. This hinged piece when clamped serves to hold the work in the fixture, and up against the locating points. It is unusual for this part of the fixture to do much driving. A wing nut with washers, is commonly provided to quickly clamp the strap or hinged cover in place. A fixture may function splendidly in every way, but it might not lend itself to rapid chucking and hence not be an economical one to use, in cases where the machining time is relatively short. In order to speed up the actual chucking operation, air operated chucks are frequently used. This method of operating a chuck does away with all wrenches, and a piece of work is released from the chuck and another one chucked in the space of a very few seconds without stopping the lathe. On operations where a short time only is consumed, air chucks speed up production to an astonishing degree.

Turret Construction

In general use to-day there are many fundamental designs of turrets, each of which has an army of satisfied users. A few of the commoner designs are, the round turret, the hexagon turret, the flat turret, the hollow hexagon, the tilted turret, etc. They are all good designs of proven merit. The choice of the design to be used would largely depend upon the class of work in hand. What is really more important than the design of the turret itself is the ability of the indexing device to stand up under long service. Even if the chuck, the turret, and the tools, are all of first class design, accurate work cannot be done unless the indexing device functions properly.

The indexing device usually consists of a steel ring which is dowelled, and well fastened with screws, to the body of the turret. For each station there is a registration hole, or slot, in the ring. This hole or slot is tapered. Into this

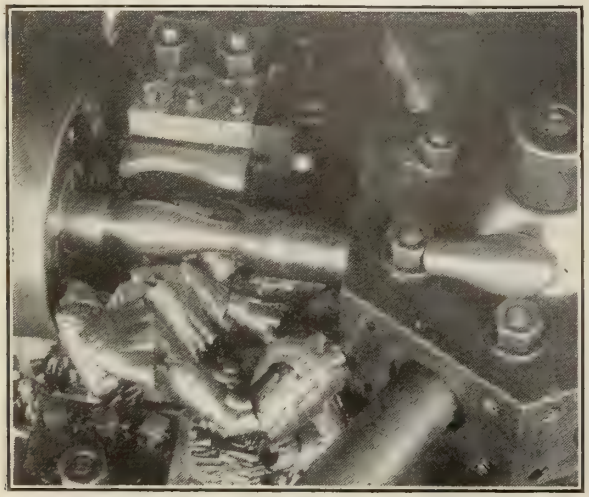

Fig. 3.—Turret lathe tooled for turning machine handles

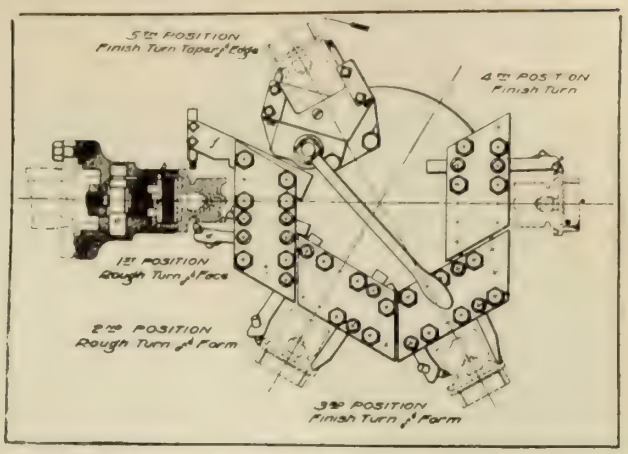

Fig. 9.—Work-holding fixture and tooling layout for second operation

opening a tapered pin, machined to fit the hole or the slot, is inserted and is usually held in place by a stiff spring. The index ring and pin are nearly always hardened and ground. There are many excellent indexing devices, but the best types are those that have ample wearing surfaces, are simple, and are ruggedly designed throughout. The locking device holds the turret rigidly in place after it is indexed, thus removing undue strains from the indexing parts.

Round turrets are somewhat limited as to the variety of tools that can be mounted on them. In fact any tool that cannot be mounted on a bar is not economically attached to a round turret. It is not usual to mount more than four bars in a round turret, which type is usually found on the smaller sizes of machines generally used on brass work for the production of small screws, rivets, and similar articles. The hexagon turret is one of the commonest types and is one of the most useful. It provides six turret faces, all of which are flat and lend themselves to the mounting of a wide variety of tools. The flat, hollow-hexagon, and tilted turrets are all adapted for special uses. Their respective manufacturers have shown many ways in which their machines can perform special operations to advantage.

General Design of Turret Lathes

Turrets are mounted on a form of lathe carriage. They are usually equipped with a large number of longitudinal feeds. It is only occasionally that a turret is provided with transverse motion. The difficulty of placing the turret again in a central position, in line with the axis of the spindle, is great, if transverse motion is provided, but this difficulty has been successfully overcome by some manufacturers.

Facing operations in a turret lathe on which the turret has no transverse feeds, are commonly taken care of in one of two ways. The first is to provide a small slide on the face of the turret. The other method is to use, when one is provided, the independent tool slide mounted on a small carriage, located between the main turret carriage and the head-stock. This tool slide is usually equipped with hand and power transverse feed. The general characteristics of the turret lathe head-stock are often the same as those of the average engine lathe.

As turret lathes are almost exclusively employed on quantity production jobs, are called upon to operate at high speeds, and almost continually, most parts of the machines are of very rugged design. The bearing of the turret carriages on the shears is long, the spindle is large and usually has an extra large hole throughout its length. There are many turret lathes on the market to-day that have many automatic features and possess many individual points of design. Such lathes often possess an all-geared head with a single constant-speed pulley drive. Gear boxes are provided that give a wider range of feeds. Automatic stops are provided, also automatic mechanisms that reverse the feed and index the turret. A lathe with all these features becomes practically an automatic, of the single spindle type. But the full automatic lathe is quite another type of machine and belongs to another subdivision of the general classification of lathes.

Some makers of turret lathes have marketed a two spindle machine, which carries two parallel spindles in the head, the axes being in a horizontal plane. The turret carries a double set of tools and two pieces are machined at once in the time it takes to complete the work on one piece on a single spindle machine.

Turret Lathes on Single Operation Jobs

Although the primary idea of using a turret lathe is to accomplish a complex operation, which is divided into several sub-operations, with one setting, it has been found very profitable to use the turret lathe on simple pieces where delicate or perishable tools are employed, Several sets of tools can be kept in the turret and when one set shows signs of needing regrinding or adjustments. the turret can be indexed to a new position and the machine can be kept going on continuous production. Although no tail stock is furnished as regular equipment on a turret lathe, many simple engine lathe jobs can be accomplished by placing a tail centre in the turret. It is not usual, however, to do such work, as it is not a difficult matter in a manufacturing shop to plan work for a turret lathe along the lines upon which it has been designed to function.

The operation which is about to be described is the machining of a reser-

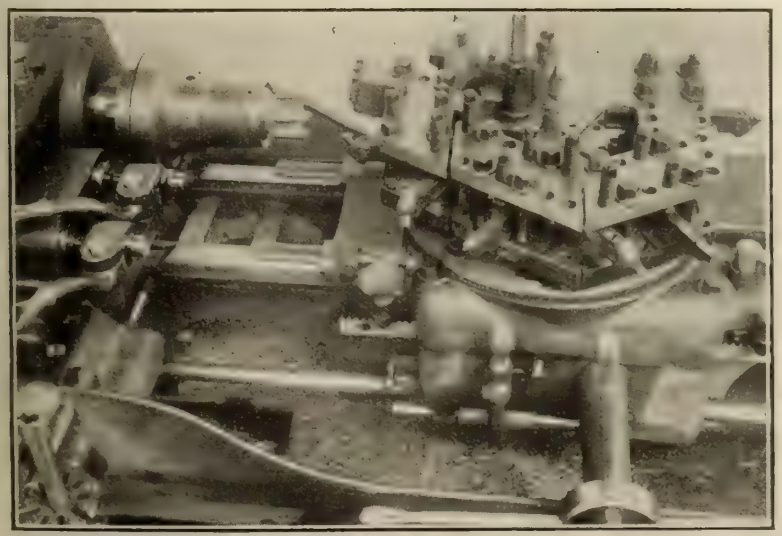

Fig. 10.—Flat turret lathe tooled for second operation on a bronze valve.

voir of an hydraulic shock absorber. This piece is shown in Fig. 1 and it will be noted that it is machined to very close limits, the tolerance being plus or minus .00025 inches. The operations performed are rough and finish boring, rough and finish face the bottom, and to turn the small pin in the centre. Fig. 2 shows the lathe tooled up to take care of this operation. The work is held in a special fixture. The machine is equipped with a hexagon turret and the machining is divided into four sub-operations. The first is to rough bore, with the tool in the boring bar shown extending from the turret face in line wth the fixture. That is to say, in Fig. 2 the turret is indexed to take care of the first sub-operation. The turret is then indexed, turning in a clockwise direction, and the bottom is faced as well as the pin rough turned. A special tool is used as is shown. It consists of four flat cutters inserted in a solid block holder, which accomplish the facing, and rough turn the pin. The tool resembles a hollow mill with inserted cutters. The next indexing of the turret finish faces the bottom and finish turns the pin by means of similar tools which are clearly shown in Fig. 2. The finish boring operation is taken care of by the boring bar and tool shown in the turret face in line with the rear end of the machine. The reservoir is made of .20 carbon steel and the lathe can produce nine pieces per hour.

Forming Machine Handles

Fig. 3 shows a turret lathe tooled up for the turning of machine handles. Bar stock is used and is fed out against a stop-bar in the turret. The piece is held in a collet chuck. It is first centred, then drilled, and reamed. These form three sub-operations, requiring in each case an indexing of the turret. Next a dead centre on the turret is brought forward to support the overhanging end of the work. Then the forming tool slide is moved up and a rough forming tool on the front, roughly shapes the handle. Next the finish forming tool on the rear of the forming cross slide finishes the forming. The handle is then cut off with a swing-over, cut-off tool attached to the side of the front forming tool. One of these handles is machined every four minutes.

Cross Boring Gas Engine Pistons

Fig. 4 features a lathe tooled to cross bore pistons. An accurate work holding fixture is attached to the spindle of the machine. In it the pistons are located in the exact position necessary for the machining. This is accomplished by the assistance of a locating bar in the turret. After the piston is located the clamp is tightened down. Then the following sub-operations occur, each accompanied by an index of the turret to bring the proper tools into position; drilling, rough boring, finish boring, and reaming. A production of fifty-five pistons per hour is maintained. These three examples of turret lathe practice have all been made on the simpler form of turret lathe that in many respects resembles the engine lathe.

Machining Bronze Valve on Flat Turret Lathe

The flat turret lathe upon which the machining operations about to be described were performed is not equipped with a cutting off slide. The turret itself, is provided with transverse feed, which can be operated by hand or power. The lathe has an all-geared head, and is equipped with a wide range of lever controlled speeds and feeds. There are many automatic stops and the turret can be indexed by power, if it is desired to do so.

The machine will work at very high speeds, holds the work to close limits, and lends itself to the use of standard tools. The job about to be described is completed with nearly all standard tools, as will be noted later.

First Operation

The part to be machined is a wing valve of tough bronze which requires fine workmanship to insure proper action when in use. The valve is shown in Fig. 5. The metal to be removed with the first chucking is shown "dotted in." Surfaces A, B, and C, must be true with each other, yet it has been found to be most economical to divide the machining into two operations. To obtain accuracy in the second operation an interesting work-holding fixture has been developed. The inside thread must be true with the surface A, and so act as to not expand or distort the thin wall. This requirement prohibits the use of a tap. Previous to what we herein term the first operation the large diameter has been rough turned and a shoulder faced. The casting is then held for the first operation in a three jawed chuck the threaded end out, as shown in Fig. 6. Fig. 7 shows the tooling layout. In the first turret position the boring and turning are done, and the bottom of the hole is faced as well as the small external shoulder. The turret is fed longitudinally into the work and then the crossfeed is engaged and the turret is fed outward as indicated by the direction of the arrow. An automatic stop determines the depth to which the boring and turning tools feed. Then the power transverse feed is automatically engaged. This combination of longitudinal and transverse feeds, permitted by the design of the turret head, allows the same tools to turn and bore, then face out, reducing the number of tools used and the tool settings required.

The second position of the turret carries the tools for finish facing. The third turret position finish turns the surface A. The fourth turret position is where the bore is finished and the necking done. In the fifth turret position the thread is chased. This is a 3⅜ inch—12 standard "V" thread. The cashing tool shown is standard equipment for this type of lathe. It is claimed to be the most satisfactory method yet developed for combining engine lathe accuracy with turret lathe speed in threading. It is entirely automatic in its action, except for the feeding in of the tool a little deeper for each cut. It cannot overrun, may be withdrawn for gauging without losing its position, and returns on the back stroke at high speed. The sixth turret position carries a ⅞ inch drill which is fed into the work for a short distance only. The entire operation is accomplished in 2¾ minutes.

Second Operation

Fig. 8 shows the surfaces to be machined in the second operation. The surfaces marked "F" in this cut are finished in the first operation. The metal shown in the shaded section is that which is to be removed in the second setting. The seat C must bear a definite relation with the edge D. To hold the valve for the machining operation, it is screwed on to a threaded plug (a) shown in Fig. 9 which gives a tooling layout of the operation. The valve is centred in the hardened sleeve (b) and is firmly seated against the face of (b), which assures that the second operation will be true with the first. In the first position of the turret, the tool (d) is fed in, to turn the wings. Then the cross feed is thrown in and the tool (f) squares down the flange and the third tool faces square the ends of the wings. Fig. 10 shows the set-up and the turret in the first position. In the second turret position the large diameter of the valve is rough turned and the groove between the corner (D) and the surface (C) rough formed. In the third turret position the wings are finish turned and the groove finish formed. In the fourth turret position the large diameter is finish turned. In the fifth position the tools fitted in an angular slide which feeds in the direction of the arrow, finishing the seat and trimming the feather edge to the definite relation required; the time for this operation is four minutes per piece. The work-holding fixture is designed to grip on the thread and finished surfaces as described. Chuck jaws would distort such a fine shell, even if they were true enough to give the accuracy required. The eccentric (C) in the work-holding fixture is turned to release the work if tightened on the thread by the intermittent cutting on the wings.

Standard Tooling

All the work in the first operation done on a standard machine and only standard tooling equipment is used. The tooling in the second operation is almost entirely standard, the exception being the holder (f) in the first turret position, and the cross-slide in position five. The latter is a standard slide but it is mounted on a special angle base and provided with a special tool holder. This example is particularly interesting from the fact that standard tooling enters so largely into the work, and shows the possibilities of economically doing special work on a turret lathe.

The mounting of a grinding wheel should be rigid, and the wheel so supported that it revolves true.

Eliminating Cold Trim Press Accidents

Danger of Working on Unguarded Presses—Repeating of Press Ram Not Always the Cause of Trouble—Unsatisfactory Experiments With Mechanical Tripping Devices—Electrical Guard Which Has Solved the Problem

By G. A. KUECHENMEISTER, Personnel Manager, Dom. Forge & Stamping Co.

THE story of punch press accidents in our cold trim department is typical of any punch press department. There was a time, not so long ago, when our operators were working at unguarded presses. Some months we had no " accidents" at all and we felt highly elated. Then the following month we had a series of injuries—fingers amputated and hands mangled. It was considered "tough luck" and that was exactly what it was—all luck. And that is exactly what any operator must trust to when operating unguarded presses. If he is lucky he will get away with it, but usually, he doesn't for very long.

A properly guarded press not only reduces accidents, it eliminates them. We have had no fingers amputated, crushed or mutilated, no hands mangled during the past year (business of rapping on wood) and we cannot see any reason why we should.

Our records of punch press accidents show that in every case the man had his finger or hand somewhere in the vicinity of the punch at the time the punch descended; not necessarily directly under the punch but close enough so that when the punch entered the die his finger or hand was injured. Then, too, we have records where a man was working along nicely, the press working fine and his hands, eye and foot (on the treadle) functioning like an automatic machine. Then it happened. Something went wrong and he made a grab for the die just as the punch came down. With the usual result. And always we were told the same story—the press repeated.

In several cases that was found to be true, at least the press did repeat when it was tried after the accident. However in most cases the press was found to be in good working condition and did not "repeat" until the next man got hurt. The real trouble seems to have been that we gave the men the same chance that the "shell game" artists give the fellow who thinks he can follow the movement of the little pea.

Schemes Tried Out

All the time that this "spotted" accident record was being made we tried to find some way of reducing the injuries. We bought window cord and pullies and tried to harness the men's arms to the presses so that when the press operated the arms would be pulled backward out of danger. That did not meet with the hearty approval of the men so we dropped it. We installed a mechanical two-handed tripping device on approval.

The foreman was all in favor of it but after it was installed he always found a good reason for not putting work into that press that could not be done without using the foot treadle. The experiment was a failure and the guard was quietly "lost." Had we thrown the treadle onto the scrap pile, where it should have been put, the device would have been used.

A series of injuries that were caused for no other reason than that the operator had nothing for his hands to do after he put the forging on the die and which resulted in the meat being scraped off the finger tips led us to experiment with another two-handed tripping device. We reasoned that a man could not use both hands to trip the press and have them near the die at the same time. The experience we had with a mechanical guard that required adjustment with almost every change of dies decided us in favor of the electrical device that we now use.

Fig. 2.—Same press shown in Fig. 1. Note position of operator's hands when tripping press. Eyes protected by goggles.

Protection Guaranteed

The guard, or tripping device, consists of a 220 volt solenoid direct connected to the clutch pin. Two push buttons placed on the frame of the press are connected in series and must be pressed at the same time to energize the magnet. A cut out switch on the top of the press which is hooked onto the ram breaks the current flowing through the solenoid as soon as the ram descends and makes it impossible for the solenoid to again become energized until both buttons are released and again pressed.

That feature makes it impossible for the operator to plug the buttons and keep the press going continuously and prevents "repeating." The location of the solenoid and push buttons is such that it never interferes with changing dies, removal of bolster plate, crank, shaft, pulley or fly wheel and only in case of a complete over-hauling of the press is it necessary to remove any part of the tripping mechanism.

The change from the foot treadle to the push button control of course brought out objections of various kinds. The first difficulty encountered was with the clutches. It was found on some presses the solenoids would not pull the

Inspection of Special Shaped Castings—The Noon Hour Problem—Non-Slipping Wrench—Counterbalancing Overhanging Work While Machining—Offset Drilling Device

By DONALD A. HAMPSON

SUPPLEMENTING the very complete article on inspections systems for the average shop, there might be told the method we adopted on some castings of rather special shape. Roughly, these castings were a 2 inch cube, solid, with several short arms projecting at different angles from the cube. After boss holes had been drilled in the arms, a number of holes were drilled in the center cube, using a box jig which located the piece from the boss holes. As the center holes cut up the cube pretty well, the latter could not be cored.

Surface inspection seemed to be the only way to determine how good a casting was until the piece was nearly done and then rejection followed if the cube was not clean in the center holes. The castings were turned out on a moulding machine and the foundry was running on a standard mixture, so the variables were concentrated in that center cube with its sponginess or lack of it, We found that the surest check was to weigh the castings as they came into the shop; an ounce under weight was suspicious, though surface inspection often showed this loss as careless grinding, but two ounces under foretold a spongy center every time.

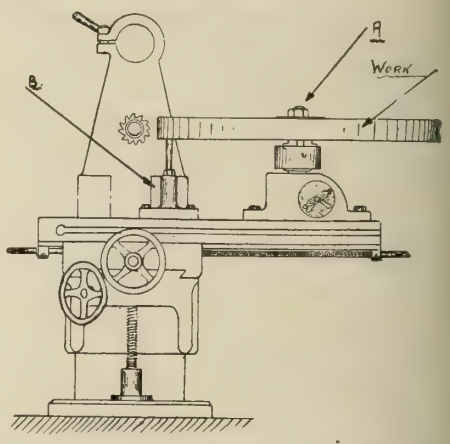
Noon Hour Problem

How true to life is that one superintendent's experience with the noon hour problem! Give a bunch of men and boys a little time and they are sure to stir up mischief or conceive labor agitations. And then the ball playing—the exertion and excitement, heated bodies, waiting 'till the last bell rings and rushing in with one fellow way behind who has to chase the last fly over the fence, then the discussions and drinking for an hour or two. I played ball that way myself, giving it up finally because I noticed that I was more tired from the strenuous exercise crowded into a few minutes than from standing all day in front of two lathes.

The reading room solution is good—the very best. If you can get men to read anything other than yellow journals you are making progress and helping them to better themselves. If you can get them to read something along their line of work, you are doing even more. Books, periodicals, trade papers, house organs—what appeals to one does not appeal to another but all of those named will help the individual to help himself. I recall going into a foundry one noon and there seeing a lad comfortably stretched on his back in the curve of a wheelbarrow which was tilted against a heap of sand—said lad was reading his correspondence school papers; he had the right idea, that of resting his muscles while exercising his mind. Find a person who has exchanged the cigarette habit for the study habit and you find one whom it will be impossible to keep from advancing.

In one plant that I know of they have solved the noon hour problem pretty well by making that "hour" thirty minutes. That extra time is taken off on Saturdays. There is not much time for fomenting around or for violent games in a thirty minute period. As a part of this plan workmen and apprentices are recruited as far as possible from those residing within a thousand feet of the plant; these men go home at noon—out of sixty, at least half reside nearby and the inducement of a warm meal is more than they can resist. Besides, they get into a different atmosphere for a short time and they return to their work with new vigor. For the men who remain, there are the shop papers which the company takes and which the men are invited to read.

This plan of a short noon period and of localizing the help has worked out splendidly. One might say that more time was required to eat and digest food but these men seem to thrive on it; as a lad, the writer used to be in a factory where there were a hundred men doing the hardest kind of physical work amid heat and dust—there were no regulations then and the men would go right back to work as soon as they had eaten, which seemed to do them no harm for they were the healthiest and most rugged of any industrial gang in town.



Tap Saving Wrench

"A tap-saving wrench" is most convenient to have around. Sometimes they are made on the principle of the friction tapping device so common for drill press use but much smaller and with only one slip surface. The great trouble with all such tools lies in their use by careless men; such men will employ them on taps larger than intended for and will then have to tighten up the slip member to drive the tap—next man that comes along doesn't know that the tool has been used ignorantly and left so and he depends on the setting to save breaking taps of a smaller size, which it will not do when tightened up so much.

If a friction, or slip, tap wrench can be made so that its adjustment is inside or is sealed—then it is all right. But otherwise the tool gives a false sense of security and disaster results. The best safety is a careful man. Careful machinists use a 4 inch or 6 inch tap wrench on No. 3 taps without mishap but they do it because their attention is concentrated on their work—not looking around the shop or talking to Bill—and because they cultivate the sense of feeling. Using but one hand on the tap wrench is the first move in the cultivation of a sense of touch. On small work, it is a good plan to hold the work in the left hand and the wrench in the right.

Overhang of Work

The writer had a large gear to cut on a small miller not long ago and he used substantially the same method as your correspondent. In addition, there was rigged up a counterbalance as shown by Fig. 1. The center bolt was tapped and a small eye bolt screwed in. In this eye, a rope was tied and carried up over two sheave wheels (of wood) set in slotted ends of a piece of timber laid across the countershaft planking. Weights about one hundred pounds heavier than the gear plank were attached—the excess being to compensate for the center head and the overhanging table.

The weight was counterbalanced by passing cable through overhead pulley and attaching to eye-bolt at A.

Thus arranged it was easy to raise and lower the knee as if there had been no 400 lb. casting on the table and the latter had not been run out to the limit. A swivel was not needed for the rope as the blank was indexed because the rope itself merely twisted that much.

The application of individual motors to machine tools has played no small part in the rapid development of certain classes, chiefly planing machines, milling machines, high-speed drills, high-speed grinders, etc., but in the view of the author the most modern application is that of the planing machine. By means of variable-speed motors it has been possible to increase the number of operations which can be undertaken at one setting, thus effecting a saving in time and power and gaining the advantage of the greater precision which attaches to the machining at one setting.

Different Methods of Forming Gear Teeth Profiles

Grinding Process Seldom Used Except for Worms—Producing Thin Gears in Punch Press—Classification According to Tooth Shape—Involute System in General Practice

By CHESTER B. HAMILTON, Jr., B.A.Sc., M.E.

THERE are two classes of ground tooth gears. Neither are used to any extent, though a few years ago it seemed as though the demand for quiet automobile rear axles would compel the use of ground bevels. The invention, however, of the Gleason curve tooth bevel gear generator—misnamed spiral bevel—solved this problem completely and economically.

The form tool method is applied to gear tooth grinding in a machine which uses an emery wheel with face formed to coincide with the tooth space, for cleaning and smoothing ordinary rough molded cast iron spur gears. As the tooth form is different with each number of teeth, a number of wheels are required to cover the range from small pinion to large gear, just as with the ordinary rotary gear cutter. The peculiarity of this process is that the form of the wheel, once established, is persistent, because the curve of the rough casting differs from the finished gear only in accidental irregularities which would not occur twice in the same place. The wheel therefore, though subject to constant wear, maintains its shape.

The generating process as applied to grinding tooth profiles takes the gear after hardening and seeks to correct the distortions resulting from the heat treatment by repeating the generating process by which the tooth was originally produced. This time, however, a very slight amount of metal is removed by an emery wheel which is given a motion relative to the work that its cutting face generates the working face of the gear tooth. The moulding generating process is used, the describing generating process hardly being applicable.

Grinding Worms

It was mentioned at the top of this section that few gears were ground. The number is in fact negligible, but this is not true of worms. Grinding is by all means the modern method of finishing worms. The modern high efficiency worms of the automotive type with large helix angles and pressure angles can be ground quite readily with the side of a flat wheel, or with the angular surface of a conical wheel. They have even been designed of such form that they can be ground with the cylindrical face of plain straight face wheels. The real difficulty in all of this class of work is not so much the grinding of the worm as the devising of means which will ensure the tooth form agreeing with that developed by the hob which finishes the worm wheel. It will be seen that the surface of the worm tooth is a warped surface which contains only one series of straight line elements. The same is true of the form of the hob—neglecting gashing and relieving. These elements of hob and worm must agree if the drive is to be efficient and durable. But the elements of the worm were created by conjugate action with the straight line elements of the face of the emery wheel which ground it. Hence the necessity for the mathematical accuracy in the face and position of the grinding wheel, the case being further complicated by the fact that the face of the wheel changes as it wears and is re-dressed.

Stamping Gear Blanks

Gears of very narrow face may be formed by stamping from sheet metal, usually brass. They are suitable only for very light duty, such as transmitting motion with practically no power, and are applicable to cheap clocks and gas, water or electric meters, speedometers, etc. Improvements in very small gear cutting machines have reduced the desirability of the stamping process. It still has advantages where the diameter of the hole is so small as not to admit a machine arbor stiff enough to allow a large bank of blanks to be cut off at once, and also where quality is a slight consideration.

The method of making pinions which corresponds to the stamping of gears, is by drawing brass rod through a die. In this case there is no punch, and the process is purely that of reduction to the desired cross section by cold drawing. This is applicable to spur gears only, of course. Very small pinions can be drawn in the form of wire, of any length and to very accurate dimensions. This process is not subject to the disadvantages as to quality that lie against the punch and die stamping. There is a true story of an instrument maker, who, some years ago, needed three brass pinions ¼ inch face by three-sixteenths diameter. He made one by cutting from the solid rod, but it took a long time, and considerable skill. In disgust he gave it up and wrote to a specialist in small gears. In reply he received a quotation on pinion wire at a few cents per foot, and a sample two inches long enclosed in the letter.

Form of the Tooth

Under the classification of gears according to form of tooth the first thing to be considered is the kind of curve. The earliest gears had teeth of circular cross section. They were simply round pegs. This form still persists to a slight extent in the lantern pinions of some clocks, and the similar roller pinions used on certain farm tractors to mesh with specially shaped internal gears on the final drive to the rear wheels.

The cycloidal tooth is of more recent date, but not used of late, and may be considered obsolete, having been superseded by the involute. The cycloidal curve is based upon the pitch circle and is traced by a point in a smaller "describing" circle while it is being rolled tangent to the pitch circle. There are two curves possible, one when the describing circle is rolled tangent to the inside and one to the outside of the pitch circle. The tooth curve uses only a small part of the whole, above and below the pitch circle, for the addendum and dedendum curves respectively. The cycloidal gear will only transmit uniform angular velocity when the centre distance is exactly fixed to bring the pitch lines of gear and pinion precisely together. This is one of a number of serious disadvantages. Wilfred Lewis, a leading authority on gear, says, "The cycloidal system cannot compete with the involute because its cutters are formed with greater difficulty and less accuracy, and a further expense is entailed by the necessity for more accurate centre distances. Cut gears are not only more expensive in this system, but also when patterns are made, the double curved faces require far more time and care. It is hardly necessary to argue any further against the cycloidal gear teeth, which have been declining in popularity for years, and the question now to be considered is the angle of obliquity most desirable for interchangeable involute teeth."

Involute Curve

The involute curve is developed from a base circle, smaller than the pitch circle. It is the curve traced by a describing point definitely located in a tangent which may be unwrapped from the base circle. Thus it is seen that the involute tooth curve can exist only outside the base circle. That part of the tooth within this circle will be made up of radial flanks or some empirical modification. The pitch circles of a pair of gears are the circles which might be imagined to replace the gears and roll together as a pair of smooth wheels without slipping. Their diameters are therefore proportional to the tooth ratio, and they are tangent to each other where they cross the line of centres. This is called the pitch point.

The pressure angle is the angle made with the line of centres by the common tangent of the tooth curves of two teeth

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Member of Canadian Engineering Standards Association.

when their tangent point crosses the line of centres. It is, therefore, the angle which the tangent to the tooth curve at the pitch circle makes with the radius at the same point. Considering the way the involute was drawn in the first place, by unwrapping a tangent from the base circle, it is evident that if the describing point, after drawing the curve may be returned to the pitch point, then the tangent to the base circle is the normal to the involute curve at the pitch point. Proceeding similarly for the other gear of the pair, and remembering that the pitch point is common to the two involutes, being their point of tangency, we see that the two tangents to the two base circles are one and the same straight line. This line is the "line of action," and the angle between it and the line of centres is the complement of the pressure angle.

Further consideration leads to the conclusion that the contact point between two involute teeth always lies in this line of action, beginning when they first mesh at the point where the line cuts the outside or addendum circle of the driven gear, continuing through the pitch point, and ending where it cuts the addendum of the driving gear. This portion of the tangent is called the line of action. The angle which it subtends at the centre of either gear is the arc of contact for that gear. The first portion of the arc of contact up to the pitch point is the arc of approach. The part from the pitch point till the teeth cease to mesh is called the arc of recession. We have been considering motion and pressure in one direction only, but as the teeth are symmetrical and motion reversible, or even just considering the back contact, it is evident there is a complete duplicate diagram which is the mirror of the first, referred to the same line of centres.

Range of Involute System

The involute system of gear tooth curves possesses very desirable flexibility in a number of its features. While the pitch circles remain tangent to each other where they cross the line of centres at the pitch point, being governed by the ratio of the two gears, the base circles may be almost anything we choose, depending on the pressure angle of the teeth. The addendum and dedendum circles may be varied considerably in distance apart depending on the depth of tooth desired, and in position relative to the pitch circle, depending on the proportions of addendum and dedendum desired in the teeth of gear and pinion. When formed cutters are used to produce the teeth all this must be decided before the cutters are made and cannot be changed thereafter. When the teeth are made by the templet or the generation processes, either with a hob or Fellows' shaper cutter, the flexibility of gear design is still greater. Then the pressure angle is fixed by the selection of the templet or the tool, but the gear blank may be turned over or under standard sizs, and when the teeth are generated they will be found to have an increased addendum and decreased dedendum, or vice versa. They will mesh and roll correctly, if the variation has not been carried to extremes.

Arc of Contact

By a selection of whole depth the length of the arc of contact is controlled. By choice of addendum and dedendum, through the turned diameter of the blank, the relative lengths of the arc of approach and arc of recession are controlled. The tooth action in regard to slippage and wear, impact and noise, varies in these parts. Tooth strength is also controlled. All pure generated involutes are undercut in the flanks, below the pitch circle of pinions and gears of less than a certain number of teeth, which varies with the pressure angle. Small pressure angles and small numbers of teeth have the most under cutting. By reducing the dedendum of the pinion of a given pair and increasing the addendum by the same amount, and taking the reverse procedure with the mating gear, a combination is produced which is very much stronger.

A feature of the involute tooth form which not only gives flexibility itself, but is fundamental to much of the preceding matter, is the fact that involute gears will operate correctly and transmit angular velocity when run at increased centre distances, but of course with increased back lash. Also two gears, both made with long addendums and short dedendums, from over size blanks on the system described to reduce under cutting, will run together. The reason is that, in effect, new enlarged pitch circles are established, of the same ratio, but the base circle remains the same, therefore the pressure angle is increased and the tooth is merely generated out of a portion higher up in the involute curve.

Different Methods

The "long and short addendum" method is not adapted to an interchangeable system of gears, but to specially designed combinations. There are a number of other ways in common use of eliminating the under cutting and weakening at the root of the pinion tooth, and the corresponding interference at the tip of the tooth, The Brown & Sharpe system of interchangeable involute gears has a corrected tooth form which eliminates all the interference and most of the under cutting for all combinations of numbers of teeth from twelve up to the rack.

This is accomplished by making an empirical modification in the formed cutter used, which thins the tips of the gear teeth and thickens the root, especially on pinions and gears of low numbers of teeth. The curve at and near the pitch line remains the pure involute. This system is very satisfactory for use with formed cutters, but, being empirical and the correction varying with the number of teeth, it is not adapted to the generating process.

The pressure angle in common use for many years has been 14-1/2 degrees. This was selected in the days of cast gears and hand-made mortice teeth, because of the ease with which it could be laid out accurately by patternmaker or millwright, without a protractor, for its sine is almost exactly one to four (.25038). Wilfred Lewis, about the year 1875, introduced the 20 degree pressure angle tooth in the William Seller Company's plant, when they were changing from cycloidal to involute. He says, "I did not at that time have quite the courage of my convictions that the obliquity should be 22-1/2 degrees, or one fourth of a right angle."

Besides having a thicker root and therefore stronger tooth, the 22-1/2 degree involute for a given depth can be made with a fewer number of teeth without interference or undercutting than can the 20 degree, just as the 20 degree involute is superior to the uncorrected 14-1/2 degree tooth. However, if the height of the tooth is reduced by using a smaller addendum and dedendum, the same result is accomplished, viz.—less interference and under cutting at low numbers of teeth, and lower numbers possible without these troubles. The Stub Tooth, as it is called, has the great added advantage of using only the best part of the involute curve, that close to the pitch line, and thereby greatly reducing the rubbing action and increasing both the mechanical efficiency and the durability. The Stub tooth is stronger than the full depth tooth of the same or less pressure angle, because the distance beyond the root at which the load is carried, i. e. if the cantilever arm is less, and the resisting cross section at the root equal or greater.

The Brown & Sharpe standard 14-1/2 degree tooth has an addendum of 1/P, where P is the diametrical pitch, a dedendum of 1.157 P, which includes a clearance of 0.157/P, or 0.05 x P' where P' is the circular pitch. This is the general system in common use throughout that part of the world using English inch measurements. Grant's system, as used in the Bilgram bevel gear generator, is the same as the Brown & Sharpe, except the angle is 15 degrees and the curve of course, is uncorrected, being a generated involute.

(To be continued)

In our issue of April 27, there appeared an item on page 42, regarding the test of a pipe threading machine at the Brantford plant of the Williams Tool Corporation. Mention should have been made of the fact that the machine was equipped with a 20in. Landis die head fitted with chasers 6¼ in. wide for the cutting of the 5¾ in. thread on 13in. O. D. pipe.

If we spent as much time planning to enjoy our work as we do planning to enjoy our holidays, the latter would take care of themselves.

Mechanical Technology of Forge Shop Practice

Interest Shown by Manufacturers in Technical Training of Youth —Art of Welding and Working Iron—Model Forge Shop Layout —General Practice Exemplified

AS AN example of the interest shown by some manufac urers in the technical training of young men, the accompanying article has been prepared. In a recent catalogue issued by the Buffalo Forge Co., entitled "Mechanical Technology," the bulk of the space has been devoted to instruction in the art of forging in its many branches. The different processes in the production of iron and the manufacture and working of steel have been dealt with in a manner that will not only appeal to the young man but to many others of advanced age who may be indirectly associated with industrial life. In commencing, the instruction covers in a brief way the development of the different classes of iron and steel. Extracts of the pages are given.

Iron is the most important of the metallic elements, silvery white in color when pure, very tenacious, malleable and ductile. Iron was first produced in America in 1622 near the James River, Virginia. It is used in the industrial arts in four forms—cast-iron, malleable iron, wrought iron and steel, each form having its own marked physical properties fitting it for a special purpose. Cast-iron is an alloy. It is often called pig-iron because of the fact that it is molded in litle bars or pigs as it runs from the furnace. The process of making this iron is that of smelting or melting the ore in a blast furnace in connection with various fluxes, particularly limestone. These furnaces are from 50 to 60 feet high and are called "blast" furnaces because the blast is forced into them. This species of iron is extremely brittle and melts at a relatively low temperaure; is crystalline in construction and can only be used for such articles as may be made or cast in molds. It contains a large percentage of carbon and usually silicon, phosphorus and sulphur. The amount of carbon varies from 1.5% to 4.5%. Malleable iron is cast-iron which has been toughened during the process of baking in an oven for six or eight days. This decarbonizes the cast-iron.

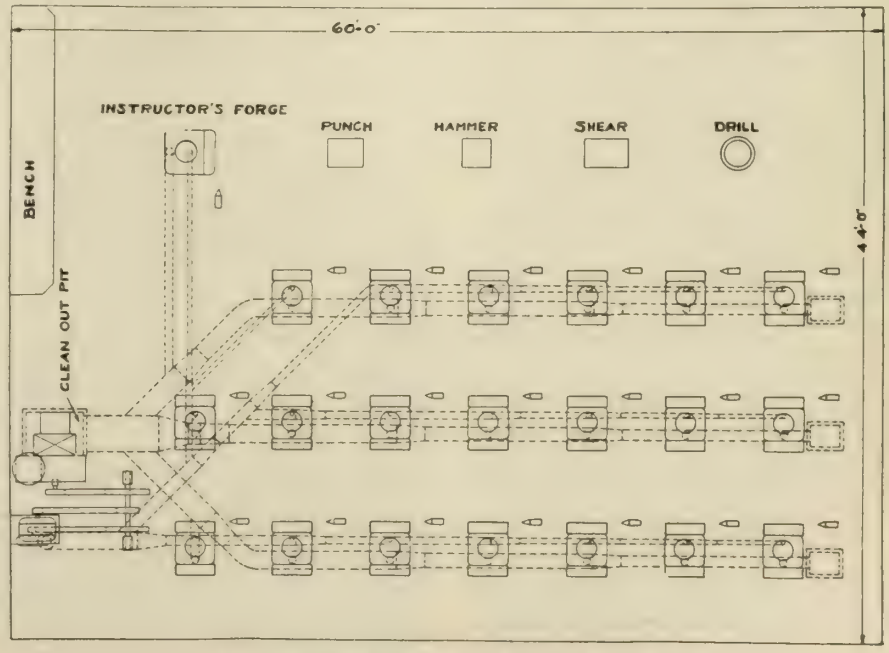
Wrought iron is the extreme of the series. It is an alloy of iron and comes the nearest to being pure, having an extremely small percentage of carbon, practically none. It is very malleable, fusing at a very high temperature; becomes pasty during a considerable range of heat; will keep in a malleable condition above a red heat, which is much below the fusing point and thus can be bent and formed into different shapes with the hammer. Iron work produced in this way is called Wrought Iron. Wrought iron manipulated when hot is said to be forged. Two pieces brought to a fusing point may be united into one piece by hammering. Pieces so united are said to be welded. It will not become hard and brittle like cast-iron as it is of a fibrous construction; it shows a high tensile strength at a fracture. This iron is divided into classes —common or refined iron and Norway iron. Wrought iron has been largely displaced for most purposes by the increased production of steel. The iron used in making the exercises in this course should be Norway iron as better results are attained than by using common iron.

The general process of making wrought iron at the present day is known as "puddling." This process was invented about the year 1780 by Henry Cort and improved about fifty years later by Joseph Hall. The method employed is one of melting cast-iron in a chamber or on the hearth of a reverberatory furnace, the flame passing over the molten metal. The requisite time for this operation is about thirty minutes. When the metal becomes melted, an oxidizing metal is added. All phosphorus, sulphur, carbon and other impurities may be eliminated by stirring. During the melting a slag forms and adjusts itself to the iron around each fibre, showing a fibrous rather than a crystalline structure. There are many varieties of various capacities; the capacity of the most common size ordinarily being from 500 lbs. to 1,500 lbs.

Art of Welding

Some metals, when heated, become gradually softer as the temperature increases, until a heat is attained at which the metal is in such a condition that if two separate pieces are brought into contact by slight pressure, they will adhere and form a single piece. Every metal is not affected in this manner. Cast-iron, for instance, does not become gradually softer as the heat is increased, but remains firm until a certain temperature is reached and then softens suddenly and goes to pieces. Any metal which softens gradually when heated, may be welded, while metals which act as cast-iron, connot be welded. The condition at which pieces of metal are ready to adhere, is known as the welding heat. The two pieces of metal properly shaped are brought to this welding heat, placed

Fig. 5.—Apprentices on forge work.



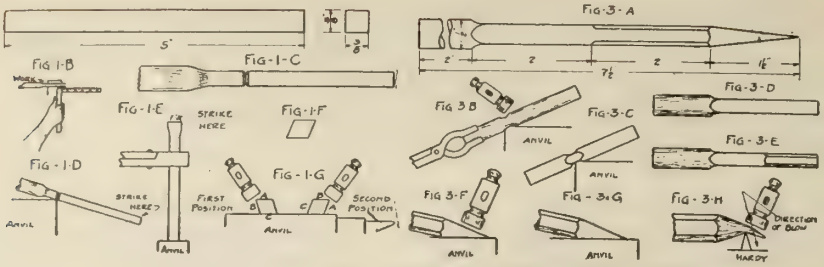


Fig. 6—General layout of forge instruction department

Figs. 1 and 3.—Some examples of modern forge practice

Exercise No. 1.

Stock—Norway iron, ½" x ½", convenient length.

One end of the stock is to be drawn until a length of 5" or more is ⅜" x ⅜". 5" of the drawn portion is then to be cut off on the hardy end, the cut end squared. The finished piece, Fig. 1 A, must be smooth, true to size, square in section and straight.

Beginning near the end of the stock, strike every other blow on a given face, and the alternate blows on one of the adjoining faces. Occasionally turn the work so that the two faces previously on the anvil may be brought under the hammer. To mark the work where it is to be cut hold the square to the edge of the hardy across which slide the stock as indicated by the arrow, Fig. 1 B, until its end is opposite the 5" mark on the square. Put down square, take up hammer, and strike a light blow. After this cut on all four sides, Fig. 1 C. Break the piece off by bringing the cut over the edge of the anvil, Fig. 1 D, and deliver a blow on the end of the piece. To square the cut end, first upset, Fig. 1 E, and then draw down to size. If it is discovered that the stock is becoming diamond shaped, Fig. 1F, instead of square in section, hammer on the high sides, Fig. 1 G.

Exercise No. 3.

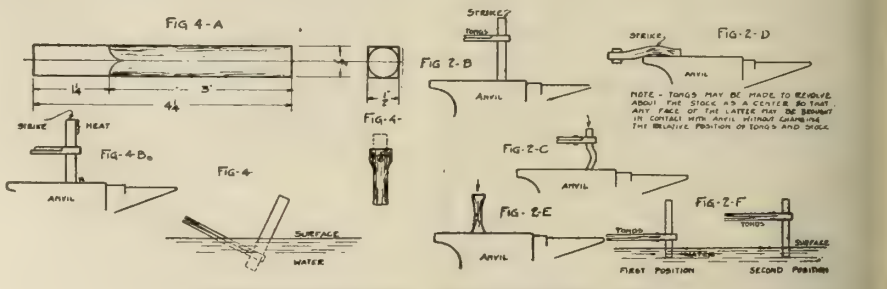
Stock—Norway iron, ½" diameter, 6" long.

A round section is to be drawn to a square; a square to an octagon; and an octagon to a round point. The finished piece must agree with the drawing, Fig. 3 A in form and dimensions.

Square one end of stock (see Fig. 3 D), make center punch mark 2" from squared end. After heating with squared end of stock in tongs, bring centre punch mark over edge of anvil and strike one blow, Fig. 3 B. Turn the stock through an angle of 90° and strike a second blow, Fig. 3 C. Draw the stock to a square section as shown by Fig. 3 D. Lay off center punch mark 4" from squared end, and proceeding as before, produce the form, Fig. 3 E. Lay off center punch mark 6" from squared end and draw the point first to a square, Fig. 3 F, and then to a round. Fig. 3 G If there is excess of stock cut it off on the hardy, Fig. 3 H. Do not let the shoulders, Fig. 3 E, cover the punch marks. Better form them a little in front of the mark and draw them back to it. When rounding the point turn the stocks; turn the stock first in one direction then in the opposite, otherwise the point will be twisted off. The point will split if drawn at too low a heat.

together and thoroughly hammered, or forced together by pressure in such a way as to bring the two pieces into contact at all parts of the weld. The weight of the blow must be governed by the size of the bar, as the blow must be sufficient to affect the metal from the surface to the center. With this precaution a good weld may be produced. It is necessary to make some of the most difficult welds at one heat, as it is often impossible to re-heat. In all welding, the greatest care must be observed to heat the piece properly. A piece of wrought iron, when brought to a welding heat, is almost white, and little explosive sparks appear upon the surface. These little sparks are small particles of iron which become separated from the bar and burn.

It is very essential to have and maintain a good fire during the process of welding. Good coal and material are among the essentials. The good fire is indispensable in order to attain the best results in welding. Tuyere iron must be well covered with coke and the fire must be absolutely free from all clinkers and well banked with green coal, burning up quickly to allow all gas to escape. Keep plenty of coke on top of the iron. Do not continually poke the fire.



Oxidization of Iron

If a piece of iron is heated in contact with air, it will absorb oxygen from the air and form a scale, upon the surface which is known as oxide of iron. The hotter the iron, the more rapidly this scale will form. The scale does not adhere firmly to the iron and cannot be welded. Two methods are used to guard against oxidation. In the first it is accomplished by having a thick bed of fire for the air to pass through before coming in contact with the iron and by maintaining a moderate blast. The second method is by coating the surface of the iron with a substance called flux, which lowers the melting point of the scale and makes welding easier. This flux is formed by a fusible mixture which offers protection to the iron. The most common flux for iron, is clean sharp sand and borax; the latter is used for fine work and steel. To weld steel is quite a different proposition, for the welding temperature of steel is, on account of its greater fusibility, considerably less than that of iron. There are so many different kinds of steel that the same rule will not apply to all of them. Cast tool steel is the most difficult to weld.

Scarf or Lap Weld

This weld is the one usually adopted by smiths and is the best when it is practicable. For most welding, the ends of the pieces must be so shaped that when welded together, they will form a smooth joint. This shaping the ends is called "scarfing" and the shaped end is called a "scarf." The scarfs should be so shaped that when placed together they will touch in the center leaving the sides open. In this way the scale is forced out between the pieces. If the pieces should join on the sides and leave the center hollow the scale would be imprisoned, making a bad weld.

To Be Continued

Figs. 2 and 4.—Other examples of forge work.

Exercise No. 2.

Stock—Norway iron, ½" x ½", 5" long.

Stock is to be upset to 3" in length. The finished piece, Fig. 2 A, must be sound, must be square and uniform in section. True to size, straight, and smooth.

The stock having been brought to a white heat, blows are to be delivered as shown by Fig. 2 B. One result of such blows is illustrated by Fig. 2 C. The stock may be straightened without changing the tongs, Fig. 2 D, or the tongs may be changed to one end. A second result of blows, Fig. 2 B, is shown by Fig. 2 E. This may be overcome and the piece upset evenly, by slightly cooling the ends, Fig. 2 F. Do not work the stock after it has cooled to a bright red heat. Strike true or the stock is likely to fly from the tongs, endangering your own safety and the safety of others. Do not attempt to straighten unless the stock is hot. In straightening be sure that the work beds well on the anvil before striking it, otherwise it is likely to fly. Do not take so much time in cooling that, Fig. 2 F, the body of the stock will become cool.

Exercise No. 4

Stock—Norway iron, ½" diameter, 5" long.

A piece of ½" round stock is to be upset until a portion of its length is large enough to form a ½" square. The finished piece must agree with the drawing, Fig. 4 A.

Make a center punch mark 2" from one end and heat from end to punch mark. Apply the tongs to the side of the stock before taking the latter from the fire. If the portion heated is too long, cool to punch mark, Fig. 4 C. In any case cool the extremity of the heated end slightly, to avoid the effect illustrated by Fig. 2 F. Strike as shown by Fig. 4 B. Continue to upset until the enlarged portion is about ⅝" in diameter, Fig. 4, then draw to a square. If when down to size, the corners are not sharp, upset again. By drawing they will become sharp. The square portion completed, finish the opposite end, A, Fig. 4 B. If it is necessary to cool the stock to the punch mark, Fig. 4 C, give it a very slight up end motion, so that the change from hot to cold may not be too abrupt. Otherwise the stock is likely to crack on the line of the surface of the water.

Overcoming Cause of Skin Infection Trouble

Research Work in Connection With Skin Diseases of Industrial Workers—Penetration of Oils Carry Bacteria Beneath Surface—Sanitary Conditions Should be Encouraged

THROUGHOUT the metal-cutting industries there exists a serious problem which has baffled industrial executives and metal-cutting operatives for years. Wherever certain liquids of oil or soap content are in use as aids in metal-cutting and metal-working, this problem—the scourge of boils and sores from skin infection—is encountered.

While there have been occasional attempts to overcome the infection, these efforts have met with little success. Nor has there been available any considerable or extensive reliable information on the causes or exact nature of the infection.

Recognizing these conditions, and realizing the extreme importance to the metal-cutting industries of a thorough, practical investigation into the problem, the research staff of the E. F. Houghton and Co., undertook this difficult task, and the information to follow is the result of their investigation.

Since the nature of such research is necessarily largely scientific, much of the terminology and detailed data is not readily understandable, even to the practical, intelligent lay mind. The purpose of this Foreword, is to endeavor to outline clearly, in plain, non-technical language the aims, methods, results and practical conclusions of the investigation.

The following material was prepared primarily for the practical information of executives in the metal-cutting industries, in the hope of aiding them in recognizing and aggressively overcoming the causes of these skin infection troubles. The investigation was undertaken also for the purpose of banishing widespread misunderstanding, which has long been apparent, as to the erroneous belief that cutting liquids are primarily responsible for the various forms of infection among metal-cutting operatives.

The pathological side of the subject involved required the aid of some of the leading bacteriologists of the world. Inasmuch as important portions of this research were carried on by these scientists, the compilation of the data involved must necessarily include considerable scientific phraseology. The language of the scientist, however, has a tendency to confuse the lay mind accustomed to directness and the use of simple terms of expression. Obviously, it is impossible to present a treatise on a subject of such a scientific nature entirely in non-scientific phraseology. We have minimized this feature in preparing this treatise by keeping always to the fore our purpose of aiding the industries in a practical way.

Copyright by the E. F. Houghton Co. and reprinted by their permission.

I want it to be distinctly understood that we have not come to our conclusions solely through what might be called "theoretical knowledge," or "laboratory experimentation." When theory has differed with practical results, we have discarded the theory. Boils and other skin infections and irritations of those engaged in metal-cutting has been prevalent in varying intensity ever since modern methods of cutting metal with the aid of oleaginous, or saponaceous, liquids, or "refrigernats," have been practised. The blame has naturally fallen most heavily on the cutting liquid, the consensus of opinion being that the cutting liquid breeds bacteria which it conveys to the skin of the human being engaged in using it as a cutting medium. This opinion, however, is not supported by the facts.

Unprejudiced Investigation

Our staff has long known this belief to be erroneous, or only partly true, at the most. The cause of skin infection or irritation among metal workers had never, however, up to the beginning of the late war (to the best of our knowledge and belief,) been intelligently or comprehensively investigated by any organized body of unprejudiced investigators other than our own staff. There have been investigations by individuals it is true, but the results of these investigations seemed but to increase the doubt as to the cause, or increase the erroneous belief as to the culpability of the cutting liquid.

The research made by our staff previous to the war had been largely for our own manufacturing purposes and its results had never been given wide publicity. It had been sufficient, nevertheless, to attract the attention of the Government and to lead to a Government request for a full and exhaustive investigation. With the speeding up of the metal industry at the declaration of war had come particularly virulent and widespread outbreaks of skin infection among metal workers. This was a pronounced handicap to the nation's need and the Government's munitions program.

The tremendous demand on the metal cutters could not allow of this outbreak going unchecked, if it could be checked. So our staff was requested by the Government officials to make an independent investigation of the subject. The theory which the investigation took as its premise was that the demands upon the metal workers had so increased their hours of labor as to shorten their hours of cleanliness and that infection followed uncleanliness through the operation of a natural law.

The task was to determine the character of the infection—whether bacteriological or otherwise—and trace it to its source. The generally accepted theory was that the bacteria were bred in the decomposition of fatty acid oils. It was, therefore, the conclusion that pure animal oils were the most prolific sources of complaint. For a time this theory seemed to be sustained, and there is today more complaint from the use of No. 1 Lard Oil than from any other oil.

Nevertheless, we soon established the fact that the infection epidemics were breaking out in places where pure animal oils were not in use, that in many plants where No. 1 Lard Oil was in use there was slight trouble experienced from the infection, and that the epidemics were occurring more or less irrespective of the variety of oil used. Our investigation was organized under the direction of Mr. Louis E. Murphy, vice-president of the company, who is in active management of the oil department of our concern, and our chief chemist, George W. Pressell.

Laboratory and Field Research

Bacteriologists of world fame were employed and placed in collaborative effort with each other, as well as with our research staff. A number of other scientists and bacteriologists of lesser note and students were employed to aid and supplement the work of the chief investigators. Field investigators were also engaged and an extensive program of intensified investigation laid out. We also conducted correspondence, including many thousands of personal letters, to obtain the co-operation, advice and experience of the men in the various industries concerned.

The office man's opinions were of course eliminated, and those of the practical man, were he proprietor, superintendent, foreman or workman, secured. This effort laid special stress on getting the views of men afflicted, those of their attending physicians, plant surgeons, etc., etc., and descriptions of the methods employed to effect prevention and cure. The correspondence also approached every oil manufacturer of any prominence in the English speaking countries, soliciting his co-operation on the solution of this very important problem.

The investigation was the most exhaustive and minute ever conducted by our staff and nearly a year was consumed in pursuing it and collating the manifold sections of the investigation. When it was finally completed, and the Government had been informed of its result, we came to the conclusion that we owed it to the industries that we contribute the results arrived at, for the benefit of the metal-working industries

in general. This treatise is the outcome.

The results and conclusions can be briefly summarized as follows:

The infection is bacterial. The bacteria, or germ, is not present in the oil, no matter of what variety or character the oil may be, but exists on the human body.

The germ has no power to create a boil or sore until it has secured ingress to the skin; or until the skin is broken or some means arise by which the bacteria can attack the flesh. All cutting oils have skin penetrative powers. This property of penetration is due to the high thermal conductivity of such oils; i.e., their ability to convey heat from the point of generation to the atmosphere. The oils can therefore penetrate the skin, and they do actually penetrate through the pores.

They penetrate the skin of hairy persons much more readily than the skin of those who are devoid of hair, because hairy skins are more vulnerable through the superabundance of capillary pores.

The oil, in penetrating the skin through the pores, carries with it the bacteria which exist naturally on the surface of every living body. The bacteria also secure entrance to the skin through minute punctures made by metal chips which are carried in solution by the oil to the human body. Many of these chips are so minute as not to be discernible to the naked eye.

These epidemics of boils are more prevalent in hot weather, or under heated woring atmospheres, than in cool weather and under cooler working atmospheres. The sores are not always precisely similar and the bacteria are not always the same. Sore-producing bacteria have been found in oil, but only in oil which has been used at least once, and not in the fresh oil as it is received from the manufacturer.

Unsanitary Conditions Serious Factor

Conditions as to sanitation are highly important, and the investigation proved conclusively the value of proper sanitary measures. The breeding of such bacteria has been traced to unsanitary conditions existing in the establishment where the oil is used. It has been found that workmen often expectorate into the oil as it passes through the machine, spit into the oil tanks, throw garbage or other filth and refuse into the oil, and otherwise contaminate it while it is in use.

Some oils encourage this bacteria breeding, when contaminated, to a greater extent than others. The worst offenders are the oils commonly known as "parafine oils." It must not be inferred that we mean parafine base oil, or oils made from parafine base crude. The distillates from parafine base crude are among the oils least culpable in this respect. These parafine oils, which are the most favorable culture media, are the ones produced in the process of pressing parafine wax. The actual difference between these bacteria-carrying parafines and the other parafines is that the former are oils pressed from residuum matter while the others come over the still in the distillation.

The most practical preventive of these epidemics of sores is cleanliness on the part of the operatives. The operatives should be instructed to wash up with pure soap; to avoid the very common practice of smearing the body with oil before washing, and to wash as frequently as possible. They should wash every four or five hours on the average and at noon as well, and before supper when they work overtime, as well as when they quit work. They should be taught to change their clothing at least twice a week and wear clean overalls and working clothes. The overalls should be washed at the regular periods set by the time it takes a pair to become soiled. Soiled underclothing, linen and outside clothing help to deposit germs on the skin. When the clothing gets saturated with oil that is permeated with minute metal chips, the rubbing of the clothing allows the metal to abrade the skin, thus affording a place of ingress for bacteria.

The skin of the metal-working operative is no more bacteria-infested than that of any other human being or worker. The metal operative is, however, more exposed to conditions which give the bacteria opportunity to get under the skin and do harm.

Disinfectants and Germicides Ineffective

Extensive study of the possible effectiveness of disinfectants and germicides shows little practical result from their use.

The benefit to be derived by incorporating in the oil socalled "disinfectants" or "germicides" is negligible. It is a fact, however, that Carbolized Cosmoline, applied to the skin after washing, acts as a preventative of the bacterial infection in question. The carbolic acid content of this preparation, being of a germicidal nature, kills the germs, while the Cosmoline, being of the petroleum family, spreads an oleaginous film which protects the pores from impregnation. Carbolized Cosmoline is, nevertheless, not infallible as a preventative and will most likely fail unless hygenic, sanitary and cleanly precautions are taken. The oil must be protected against contamination of any kind. This includes the best and most modern methods of minimizing the amount of metal chips which are carried off in the oil.

Epidemics of sores are likely to occur in any plant where metal-cutting is done with the aid of oil. Previous immunity from such epidemics is no guarantee for the future. It happened on several occasions during our first inquiry that we were informed at a plant that no such thing as sores had ever been known there. Then, after a short time, we received from the same concern an inquiry as to how we were getting along with our investigation. They added that they were experiencing an outbreak of sores on their employees "for the first time."

Oil plant workers, except those engaged in parafine pressing plants, are not very susceptible to the infections in question. The Houghton employees, for instance, rarely experience sores and, when they do, the trouble can never be ascribed to the oil with which they came in contact, or to the bacterial infection above outlined and described in the following treatise. Neither has any other oil works that we know of ever had an epidemic of such bacterial infection or irritation due to oils, the parafine oil pressing plants excepted. We found the epidemic to be quite common in the pressing plants of parafine wax manufacturers.

The immunity of the Houghton plant may in some degree be due to the dermatological phenomenon that these sores never occur upon the skin of a negro. The skins of dark, swarthy people, such as those from southern climes or those whose immediate ancestors come from southern climes, seem to be similarly immune. This may be for the reason that the hides of all tropic-bred animals —including the human animal—are tougher and more difficult to penetrate than the hides of animals raised in cooler climates.

The main reason for the absolute immunity of the Houghton workmen from such sores and irritation, we believe, is that the nature of their work compels frequent washing and attention to sanitary habits. They are continually impressed with the fact that the products they turn out must be absolutely clean and sanitary. They know that the prevention of infection or contamination of the oil is a primary principle of oil manufacturing.

In conclusion, we unhesitatingly say that the elimination of these sores is essentially a matter of the proper education of the workmen. The education is most satisfactorily given by means of posters placed in prominent places throughout the shops and in the washrooms. These posters will lose their value, however, if not replaced from time to time, kept clean and in an attention-attracting condition. Workingmen become so accustomed to their environment that they gradually come to pass an important notice by, without deriving any impression. They are very likely to forget even a fire notice which they see right before their eyes daily.

If there is an internal publication distributed among the employees, it should feature the prevention of sores from time to time, just as much as it undoubtedly does the prevention of fire and accidents. Cleanliness should be preached at all times. A polyglot working force, with workmen of many nationalities, offers its own problem as to the dissemination of this infection-prevention information.

The final word is this, that no matter what may be the source of the cutting oil you obtain, it does not, if it comes to you fresh from the manufacturer, contain bacteria which will create these boils. Oils that decompose readily, such as animal oils, will supply nourishment to such bacteria. Parafine oils will give the bacteria the greatest aid in getting under the skin and into the flesh, but even they do not, if fresh, contain the bacteria when received.

ELIMINATING COLD TRIM PRESS ACCIDENTS

(Continued from page 21)

the clutch bearings and remedied. Some of the men found it difficult to get out of the habit of using the foot to trip the press but after a few days with the new device, that was overcome and in a short time all objections were forgotten and everybody was satisfied.

It had been freely prophesied that production would suffer. The foreman, of course, was the first man to make the prediction that he could not get out enough work and that he would be blamed for the slowing up. He was told, and shown with paper and pencil, that even though his production was decreased fifteen per cent. the saving in the cost of lost fingers and hands would take care of the loss due to fewer forgings being trimmed per day. The foreman was willing to use the new guards when he was assured he would in no way be held responsible. We did not look for a permanent decrease in production and results proved we were right.

The first few days of course showed a decided decrease in production but as soon as the men became accustomed to the new way of tripping the press and devised new methods of handling the forgings it soon came back to normal. In some cases there is a permanent decrease in the number of pieces put through the press but the job is free fom the old time danger which more than makes up for the loss. In many other cases production has increased. A general average up of all jobs shows that production has not suffered and the elimination of injuries removes a charge against the department that formerly increased the operation expense considerably.

If the proof of the pudding is the appearance of the dish after the meal then the record of a department with twenty presses operating for twelve months, showing only two injuries—one due to a wrench slipping and the other to a blow from a hand hammer— should be considered sufficient proof that guarded punch presses and careful supervision by the man in charge does eliminate "accidents" and that such things need not be "part of the day's work."

Avoid an accumulation of material around the machine. A clear floor provides freedom of movement and prevents many accidents. If it is necessary to have parts about the machine, see that they are properly and firmly piled.

It has been estimated that there were, July 1 last, 12,588,949 motor vehicles in the world, of which 10,505,660 were in the United States. No other country reaches 500,000, Great Britain being second with 497,582, Canada third with 463,448, France fourth with 236,146 and Germany fifth with 91.384. All of Europe is credited with 1,110.990, or rather less than New York and Pennsylvania combined.

Introducing

TRACEY MANES

TO BE foreman of the tool room at the Massey-Harris Co., Toronto, you must be able to deliver the goods, and that is why Mr. Manes is where he is to-day. He has had a varied experience since he was born in Orno, Ontario, back in 1868, and although he was only able to secure a general public school training, he has made the most of his time and opportunities since that time.

After leaving school he devoted about four years of his life to farm work, and cutting timber in the bush. He would summer on the farm and winter in the bush, but soon the engineering bug got him, and he came to Toronto 33 years ago to start as apprentice in the tool room of the same firm he is with today.

He served his time, but left the Massey-Harris Co. in 1896 to go to the Canadian Fairbanks Co., Toronto, working in their tool room. From here he moved to the Canada Foundry, Toronto, but moved again and landed at the Elliott Paper Mfg. Co., Toronto, as general foreman of factory, supervision of machinery, repairs, etc.

During all these moves he was lapping up all the information possible, and in 1910, he went back to his old love, the Massey-Harris Co., as a lathe hand. The old familiar Irish saying held true, for in 1911 he was made assistant foreman of the tool room. On May 28, 1914, he blossomed out as a full-fledged foreman having held the position ever since.

Mr. Manes has wonderful patience with the rising gerenation, and helps the boys learning their trade all he possibly can. This has made him a favorite with the boys up at the Toronto Technical School, because for the past five seasons, he has been showing them in the evenings how to become capable toolmakers.

Mr. Manes belongs to the Masonic order, and is also a member of the Oddfellows, but best of all he is a dyed-in-the-wool baseball fan, who roots for the home team on all occasions. "Young men to-day have an excellent chance to advance if they will only stick to it," says Mr. Manes, and we agree with him, for it is the same "Sticktoitiveness" that has placed him where he is to-day.

IMPORTANT VOLUMES

The first volume of a most important work, "A Dictionary of Applied Physics," edited under the supervision of Sir Richard Glazebrooke, K. C. B., F. R. S., will be ready for Canadian distribution about June 1st by the Macmillan Co. of Canada, Toronto. This work will be published in five volumes. Succeeding volumes will appear at intervals of from two to three months. It is arranged as follows:

Vol. I. Mechanics, Engineering and Heat.

Vol. II. Electricity.

Vol. III Meteorology, Metrology, and Measuring Apparatus.

Vol. IV. Optics, Sound, and Radiology.

Vol. V. Metallurgy and Aeronautics.

This is the first attempt which has been made to bring within the compass of a single work the latest results of research, and the most approved methods in all branches of the subject. It should prove invaluable to all manufacturers who are vitally concerned with the question of physics as applied to industry, which has grown enormously in the past few years. The experience of the war has enforced more strongly the lessons thus taught, and the importance of Applied Science is now universally admitted.

To find the diameter of a pump cylinder to move a given quantity of water per minute, divide the number of gallons by 4, then extract the square root, and the product will be the diameter in inches of a pump cylinder required to do the work at a piston travel of 100 ft. per min.

Recent Developments in Mechanical World

Cleaner Workshop Methods

AN INGENIOUS method of purification is now carried out in many industrial establishments for the removal of dust and refuse. If the stuff is combustible a double purpose is served by consigning the material to the fuel quarters. The main features of the installation are a special exhauster and separator, which work in conjunction and are connected by means of trunking, their respective duties being to draw the refuse from the various machines and then deposit it in some convenient place for handling.

* * * *

Developments in Die Casting

A SURVEY of modern die casting, which consists of forcing liquid metal under dies, reveals a great advance in the use of aluminium alloys. Dies obviate a great deal of machinery work. Parts which otherwise would be made separately and then assembled can often be combined and cast into one die casting. The castings have almost a perfect finish, free from porosity and other defects so common in sand and malleable castings. The dies themselves are fairly costly, says Practical Engineer, as they take long to build, and involve very skilful workmanship; yet where castings are used in lots of 10,000 upwards they will turn out cheaper than sand castings. In dies for parts made of white metal alloys, a high-grade machine steel is used, whilst for aluminium parts a steel with 0.40 per cent. to 0.50 per cent. carbon is used, and generally the steel is not heat treated. In weight, generally, die castings should not exceed: For zinc-tin alloys, 10 lb.; lead alloys, 15 lb.; aluminium alloys, 3 lb. The future of the industry lies in the proper development of a grade of steel permitting the die to offer greater resistance to wear and pressure.

Lubricating Air Compressors

ONE OF THE secrets of successful compressor operation is its lubrication, and it cannot be over-emphasised that the least possible quantity of oil must be used. Any excess will carbonise because of the temperatures to which it is exposed. This carbonaceous matter is sticky in the early stage of its formation, which gives it a tendency to adhere to the piston rings, valves, receivers, and may be carried even to the fuel valve parts. In its later stages the carbon forms a hard solid that interferes with the operation of the compressor. Unfortunately there is no oil which will not deposit some carbon, but there is a surprising difference in the quantity of carbon deposited by different oils. Consequently not only must oil be selected with care, but particular attention must be paid to prevent the use of more oil than is necessary. This is one of the principal reasons for arranging the stages of most air compressors with the intermediate stage at the bottom, says a writer in Lubrication. In this construction there is always a pressure opposing the tendency of oil to work up into the air space from the lowest cylinder wall where it is thrown by the crank pin. In fact, at least one manufacturer has found it necessary to cut down the quantity of crank case oil so much in order to keep it from getting carbon and only a little vapour. Several cases of air compression explosions which have been investigated carefully suggested that the cause was excessive carbon deposits in the piping, which had greatly restricted the area of the passages. The real cause of these explosions is still to be explained satisfactorily, but it is to be noticed that practically all occurred in piping remote from the compressor, and hence at places not subjected to the highest temperatures.

Hardening High Speed Steel

FOR HIGH-SPEED steel the salt bath hardening method is held to produce a cleaner tool than muffle furnace hardening, but there are disadvantages, such as quenching temperature is too low, soft scale is ofttimes produced, also blistering and pitting, and the pots used are very shortlived. Pack hardening with charcoal gives a tool free from scale, but here again are disadvantages. The quenching temperature is too low, and the tools are carburised. The cutting edges of the tools, due either to higher carbon content of the surface, or the tools coming into contact with each other also at times melt. Other methods of packing have been tried, but without success, says a writer in Practical Engineer. Neither has any success been achieved with a lead bath hardening. There is difficulty in controlling the time of immersion, and at a temperature of 2,200 deg. Fah. volatilisation inevitably ensues. If hardening is done by heating in semi-muffle furnaces, pyrometers should be used. A great advantage of this method is the high temperature attainable, resulting in a great degree of red-hardness, and almost complete solution of the carbides. A set-off, however, is the scaling of the tools, to lessen which a thorough pre-heating and the proper mixture of fuel and air in firing is essential. Successful hardening is obtained by employing two pre-heating furnaces, one at about 1,000 deg. Fah., and the second at 1,700-1 800 deg. Fah. There is no scaling in the former, and in the latter pre-heater, the steel oxidises, requiring less time to bring to heat, and thus reducing scaling to a minimum.

Research Work on Cast Iron

DEFECTS associated with unsoundness, porosity and shrinkage continue to trouble the metal working industry. Examples of such difficulties in heavy and light castings and in malleable work have been submitted and help sought in the remedy of same. The variable practice in cupola operations, in the preparation of facing and core sands for definite types of castings has again been illustrated in several of the problems submitted. The synthetic preparation of sands and linings for high-temperature work is under consideration by the British Cast Iron Research Association and trials suggested based on recent refractory research results. In the domain of the light castings foundry problems connected with mixtures, and treatment for light castings subject to shock have been investigated and advice given. Certain abnormal structures in heavy and light grey iron and malleable castings have been submitted for investigation and advice tendered. Problems associated with the chemical analysis and testing of cast iron have been dealt with. In many of the above cases data of a specially useful character has been obtained such as is of service to the researches on moulding sands, cupola linings, shrinkage and draws and the pig iron grading problems. The influence of design has been of signal importance in some of the troubles experienced, and the full particulars supplied in several of the most intricate problems under investigation have materially helped the director in his conclusions. Work is proceeding on the main problems of research and data of practical assistance in the carrying out of these somewhat lengthy researches continues to arrive from members.

* * * *

With a total of 80,853,000 lb. copper U. S. exports in March showed a marked gain over recent months and registered the largest total for any month in nearly two years. Imports of both tin and zinc were larger. Tin imports for March at 15,783,000 lb., have been exceeded only once in the last two years, according to the Department of Commerce.

Automatic Seam Welding in Making of Tubes

Material Must be of Suitable Composition—Finger Arrangement Prevents All Twist or Curl When Strip Stock is Entering Rolls—Compressing the Metal After Weld is Made

By J. L. ANDERSON

THE CONCLUSION of the first part of this article, which appeared in the May 4 issue, described the various details of the swaging machine and it operations in the making of steel tubing.

The action of this machine is decidedly different from that in which the cage is stationary, resulting in a series of very powerful blows which is destructive to the rolls and hammers. The dies oscillate due to centrifugal force with the hammers and thereby produce a succession of squeezes varying between 3,000 and 5,000 per feet, depending on the size of the machine and the speed at which it operates. The over sized tubing as delivered from the tube welding machine is compressed with an accuracy equal to the accuracy of the dies, and with a finish which is very much smoother than is usually possible with the draw bench.

Obtaining Accuracy

The swaging speed on full length tubing will usually be in the neighborhood of 30 to 40 feet per minute. The swaging machine is used often times in conjunction with the draw bench in order to reduce the diameter of the tube sufficiently to pass through the dies so that the dog of the draw bench can grip it. The swaging machine when equipped with formed dies is used very extensively for swaging tubes which are to be tapered or changed in form. It is sometimes necessary to perform an operation of this kind by passing the tube through successive dies in order to produce the final form. If tubing is required to be brought to accurate dimension externally and internally, the operation must be performed on the draw bench, and for this purpose the draw bench is usually fitted with what is termed a back bench. This is an extension of the bench in order to provide support for a rod which is termed the triblet rod, and carries on its end a hardened steel plug which is the exact internal dimension of the tube. This dimension being considerably smaller than the tube allows for the tube to be passed over the plug, previously lubricating the plug and tube, and when entered in the die or dies is drawn down to finished dimension passing through the annular space between the triblet and the die, thereby being brought to proper dimension both internally and externally. Sometimes it is necessary to perform this in more than one operation, if the reduction required is excessive.

The drawing speed with properly lubricated dies is usually in the neighborhood of 40 lineal feet per minute, the machine always requiring two men for maximum production. When equipped with a roller die head the drawing of various shapes of tubing from round tubing is possible, squares and rectangles being most common.

Straightening Finished Tubes

Tubes coming from the swaging and drawing operations are never absolutely straight and must be straightened, which is usually accomplished in a straightening machine, or in some cases by hand straightening over a block in the usual manner. The straightening machine, however, makes possible very much larger production at less cost and produces uniformly straight tubing without danger of kinking or flattening. This machine is usually of the ten or twelve roll type, with two sets of rolls at right angles to each other, three rolls in each case being power driven, with the final roll in each set adjustable, as are the two idlers. This arrangement simplifies the straightening operation and makes possible the straightening of tubes at speeds of 100 to 200 feet per minute, depending on the size.

After the swaging and drawing operations the crop ends, if any, are removed from the tubes by the tube cutting machine which carries a swinging high speed saw, belted to a motor, the motor being mounted on the base of the swinging head carrying the saw. The saw used is a special saw for cutting soft steel at high speed, and is driven at from 3,000 to 4,000 R. P. M. The saw is actuated by a foot treadle operating through a compound lever which advances the saw, thereby severing the tube. All moving parts above the table are covered by removable guards, and provision is made to discharge the sparks and chips accompanying the cutting operation to the rear of the machine.

There is a demand for steel tubing bent in various ways, and a tube bending machine is usually a part of the equipment of every tube welding plant. Round, rectangular and other shaped tubes can be bent perfectly to any reasonable radius without deforming or wrinkling, the bending operation being in reality a drawing operation, a plug of proper type being used inside of the tubes and removing the finished bends.

The machines are always equipped with clutch pulleys for driving in both directions, and very often with power attachment for entering and withdrawing the plug, considerable power being required for withdrawing the plug after the bend has been completed, due to the gripping action of the walls of the tube upon the plug. All the operating levers of the machine are in a convenient position so that one man controls all the motions of the machine, while another is usually employed for feeding the tubes and removing the finished bends.

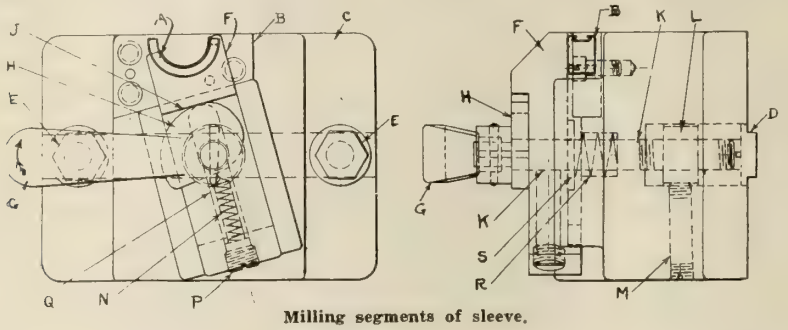
Production Time

A different set of tools is required for every change in dimension, or radius. These tools are readily mounted on the machine by the removal of four bolts, and the clamping action of the jaws accomplished in various ways to suit the particular requirements. The actual time consumed in making a bend of 90 degrees seldom exceeds eight seconds, the production of 100 to 120 bends per hour being possible. The machine as usually furnished will produce bends up to 180 deg.

The simplicity of the process of manufacturing welded tubing as described, eliminating the necessity for ponderous equipment of great cost and the numerous operations required to produce more than a million feet of tubing a year can produce tubing in its own plant for its own consumption in competition with market prices; this is particularly so if his requirement is more or less special.

The successful operation of an installation of this kind is assured by reason of the engineering assistance available for the solution of the many and varied problems which arise in production and fabrication, to say nothing of the education in the art of tube making, of the personnel responsible for the success of the undertaking, as well as the education of the employee in the operation and possibilities of the various machines.

Conclusion of a paper read before the Schenectady, N. Y., section of the American Welding Society, February 8, by the author, who is welding engineer of the Air Reduction Co.



The Boaman & Smith Co. of Providence, R. I., have recently published a series of new catalogues covering their various lines of equipment. H. 1 deals exclusively with a wide range of milling machines suitably adapted to many lines of work. H. 2. describes in detail the different styles of boring machine made by this firm. H. 3. shows a line of machinery especially designed for work in connection with the manufacture of automobiles. H. 4. is a descriptive booklet illustrating machines particularly adapted for machining of pumps and valves.

Practical Ideas for Shop Executives

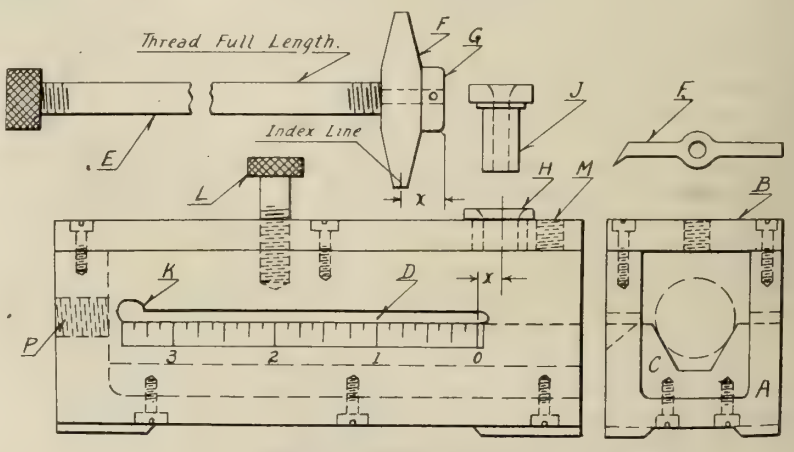
MILLING SEGMENT OF A SLEEVE

By F. Scriber

What proves to be a very quick operating fixture for milling the dovetail slot in the segment of sleeve A is illustrated in the accompanying sketch. The sleeve is here set on its edge and is indicated as A, in the fixture is a plate B shaped to receive this sleeve, this plate is attached by means of screws and dowels to the cast iron base of the fixture C which has a tongue D made as

Milling segments of sleeve.

part of it and two bolts E for holding and locating it on the milling machine. After the work is put in position it is clamped therein by means of a lever G, this clamp is unusual in its operation as a cam H is employed to advance it to the clamping position. In operating this clamp which is guided in a milled slot in the casting, the lever G is pushed in the direction of the arrow which causes the raised surface on the ram H, acting in contact with shoulder J of the clamp F, to advance the clamp to the position shown over the work.



The dowell on the cam then permits the clamp to rest while the lever causes the clamp to tighten on the work by simply tightening the cam side against the clamp by means of the screw K which is operating in the nut L into which it is thus screwed. This nut is locked in position so it will not turn by a screw M after it is adjusted radially so the screw will clamp tight with the lever in the position shown. Upon releasing this lever G a spring N backed up by a screw P held in a spring plunger Q, which comes in contact with the unthreaded portion of the screw K, causes the clamp to be forced back clear of the work while the spring R, in contact with the washer S, raises the clamp up from the work as the screw is loosened, thus it will be seen that the operation of this fixture briefly stated is as follows:

The operator puts the work in position, following which he turns the lever G which through the medium of the cam advances the clamp while at the same time tightening the clamp on the work, after which the milling machine cutter is caused to mill the tee slot in the work, the cutter in this instance being of the end mill type, held in a horizontal milling machine. Following this; releasing the clamp is accomplished by turning lever G backward which action allows the clamp to rise from the work and slide back clear of the work by means of the two springs shown, thus the work may be readily removed by hand. It will be apparent that this fixture is very speedy in its operation, and in this instance this quick action is obtained at slight additional expense in the construction of the fixture.

UNIVERSAL DRILL JIG

By Robert Mawson

The drilling of small holes in pins is often a detail that will require a number of different jigs unless care is taken in the design of these tools. A jig that has a wide range for work of this character is shown in the accompanying sketch. The base A is made of cast iron box construction, open at top and one end. A machine steel plate B is secured to the top by means of screws and dowels. Bolted firmly to the inside base is a V-block made of steel or cast iron.

Design of universal drill jig.

Through both side walls are slots D machined and at the same central height at the hole P. The front edge of one slot is bevelled and graduated for setting gage piece to desired length. The screw E is made to fit hole P and of ample length for capacity of jig.

The steel pointer F is made a sliding fit on end by E and secured in position by collar G, which is pinned on. The piece F is a snug sliding fit in the side slots. With the pointer at zero the end of gauge G is central with drill bushing. Suitable slip bushings J may be made to fit the fixed bush H. A knurled headed screw L is provided to hold pin while drilling. For drilling holes close to end of work a screw hole M is used.

ASSEMBLING STAND FOR MACHINE SHOPS

By Robert Mawson

Anyone with experience in machine shops on assembling operations will know that much time is lost in this department with shortness of parts when the work is under way. It is often found that some of the smaller elements have not been called out of the stores, the result is time is wasted by the workman either going for them or sending a helper for the missing material. Another loss of time is caused by the want of system in keeping the parts along side the job, usually a box or table being utilized for this purpose. The result is that the man has to look over many parts and pick out the one needed at the time.

We recently introduced the stand illustrated for this purpose and it has solved the problem proving satisfactory to the men also, which is often a great factor in the shop. Give the men something they want and like and it is used successfully, but give them the opposite and a score of faults are quickly found why it should not be used.

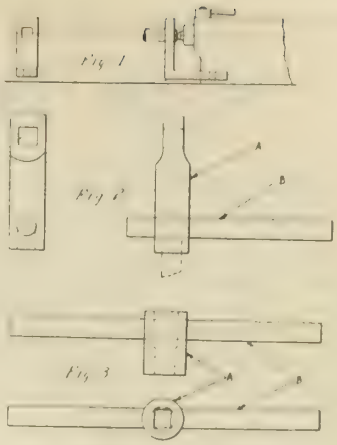
The stand is placed at the rear of the assembling table and at a convenient height for the workman. It is made with

a number of openings and also hooks which are screwed into the framework of the stand. The manner in which this device is used is briefly as follows: each of our different assemblies and sub-assemblies are routed through the shop by means of bills of material. These have recorded on them the name of each part, drawing number of each part, stock parts such as bolts, screws, etc., and the number required of each for one assembly. Further, the bill of material is made out in rotation of assembly, the words being listed on the sheet in sequence they are needed for assembling operation.

When the order goes into the shop for a number of any machines to be made and assembled, the bill of material also goes with it and the foreman sends one of his men to the stock room to draw out the various parts. These are given him on an order signed by the foreman and are conveyed to the assembling department. The man then takes out the bill of material and ararnges them on the assembling stand, starting at the upper left hand corner and where bolts, screws, and the like are neeeded they are placed in the pocket after the part in which they are attached. The large pieces are placed on the various hooks as may be seen from the cut. The reason why the small parts are placed after the part in which they are attached is so that the workman first places the casting into position and then reaching for the holding medium fastens it as required.

It is easy to see the advantage of this method as the workman has only to follow along the stand in sequence and the various elements are at hand when he wants them and also where he needs them and further he is always sure of having just the proper amount and is saved the worry of sending for missing parts as was the case with the older one employed. The cut shows the convenient

Assembly stand for machine shops.



height of the table and also the handy position of the assembling stand. It need only be added that the size of the stand would have to be changed for some work and also the size of openings for the small units as we have done in our factory, but the illustration conveys very clearly the idea of the device and could be used to advantage in almost all shops doing assembling operations.

MACHINE TAP WRENCHES

By Harry Moore

Tapping operations, when performed in the machine, call for a big variety of holders and wrenches, the design of which is determined by the particular requirements of the job. It is sometimes difficult to discriminate between a wrench and a holder and two or three of the ideas shown may not be correctly described as either one or the other, since they do not actually hold the tap in the machine, nor do they wrench it around, the movement taking place in the machine, the wrench merely acting as a stop to prevent the tap from being rotated. It will readily be understood why these have been included under the above heading, however, when it is pointed out that they are put forward solely because they are believed to be a better means than the ordinary tap or monkey wrench generally utilized in this kind of work; and these latter still retain their names no matter what they are used for. In the few examples given, only those have been selected that could be made easily in any general shop large or small.

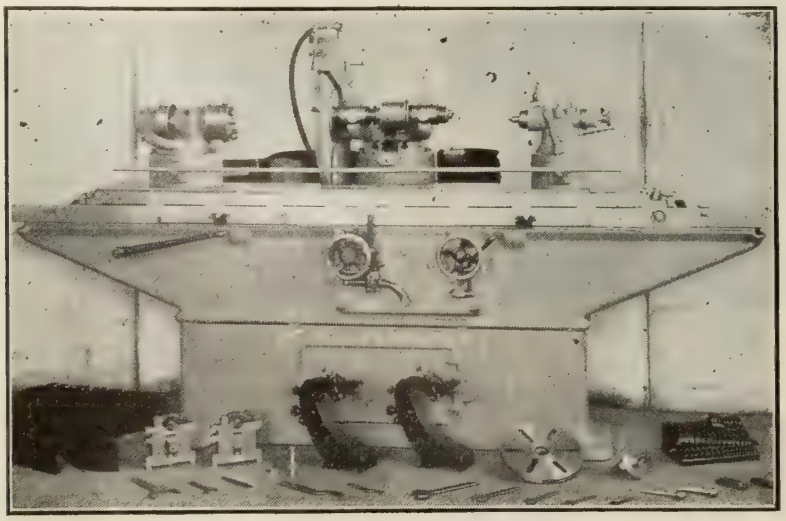
If the first example Fig. 1, a wrench for use on an engine in connection with these machines is well known. As the tap advances into the work, the end of the wrench resting on the carriage oftentimes playfully wipes everything—wrenches, calipers, etc, that may be lying there—onto the floor. Sometimes to add to the confusion, the operator finds the wrench squeezing up against the cross-slide, whereupon there is a frantic grab for the carriage wheel to release

Various types of machine tap wrenches.

tap—through the operator's divided attention—has walked off the center threatening to smash the whole business. This is not a fanciful picture by any means, and more could be said, but this will suffice to show the advantage it, and by the time this is effected the of a special wrench for lathe work that will bear against the side of the tail stock and so be clearly out of the way of everything. This wrench is just a piece of stock bent at right angles, both ends having squared holes, two or three if desired, to take the different sizes of taps. Make the wrench long enough to clear the tailstock clamping nut when backing out the taps.

Fig. 2, which is a development of this idea, is for use when tapping right up to a shoulder. It is very easy to strip a thread when a lathe is driven through the back gears, so that the careful operator sets his mark on the tap back a thread or so and finishes this distance by hand, twitching the wrench around as far as possible, and backing the lathe. The wrench in Fig. 2, is made in two pieces, A being round steel flattened out at the end, squared out for the tap and drilled for the handle B in two places, through the side and at the end, so that it can be quickly slipped out of one or the other. It is inserted in the hole at right angles when the lathe is running and in the hole at the end for finishing by hand, which latter can be done very quickly by reason of the wide swing this wrench has in comparison to the limited movement of a double-end tap wrench.

The wrench in Fig. 3 shows one way of solving the obstruction problem in a simple manner, in this case being the column of a drill press. In shops where several drill presses of different sizes are in use it is not customary to have wrenches to suit each machine, far from it, though of course this can be excused on the ground that hand tapping operations may not be a daily occurrence on drill presses. They are very frequent however for many reasons, chief of which is, it is easier to tap a piece of work already clamped down, than transport it somewhere else for the same purpose, especially when it is of such shape that clamping it is quite an operation in itself; still if it is necessary to lift the wrench off the tap square every half turn it is a question whether any actual time is saved at all.



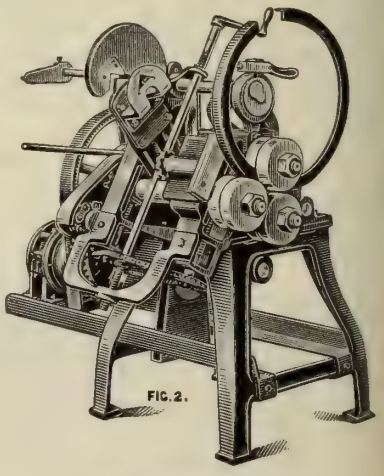
New Things in Shop Equipment

PORTABLE SAND DRILL

There has recently been placed on the market a portable drill stand for use with the "hole shooter" electric drill. With the drill vertical the combination serves as a bench drill in the usual sense. It can be swung into a horizontal position and the device can be used as an electric grinding machine, or for buffing or polishing. A large number of other applications can be made as the drill can be set to operate at any angle, by simply loosening the set screws, adjusting the drill body, and tightening the screws again. The base of the stand is of cast iron with a finished table 8 x 8 in. The upright is of 1¼ in. dia., cold rolled steel. The range of travel of the slide is 12in. and the range of travel of the rack is 3½in. The total weight of the stand is about 30 pounds. The design and construction of the stand has been so worked out that springs for controlling the travel of the rack have been eliminated. The apparatus is manufactured by the A. H. Peterson Manufacturing Co., of Milwaukee, Wis.

UNIVERSAL CRANK SHAFT GRINDING MACHINE

A machine that is designed especially for use in motor service shops has recently been placed on the market. It is capable of grinding crankshafts, pistons, wrist pins, valve seats, and stems, in addition to the regular straight and taper grinding usually done on a universal grinding machine. With an internal grinding attachment and chuck, it does internal and face grinding on such parts as individual cylinders, clutches and transmission gears. All ordinary parts of motors can be ground in the machine, excepting cylinders en bloc. By using a tooth rest, it will also grind line reamers, milling cutters, centres, boring bars and other tools. The automatic cross feed will move the wheel from 0.00025 to 0.004 inches at each reversal of the table. It is automatically disengaged when the work is ground to size. The travel is automatic and is controlled by easily adjusted dogs. The base of the machine rests on the floor at three points. This construction maintains the alignment of the table and prevents it being affected by any inaccuracies of the floor. The grinding wheel is 24 inches in diameter, 1 inch thick, and has 5 inch hole. It is protected by a heavy guard which helps to confine the spray and particles of abrasive. The machine is manufactured by the Brown and Sharpe Manufacturing Co. of Providence, R. I.



Universal and crankshaft grinding machine.

DOUBLE CRANK TOGGLE PRESS

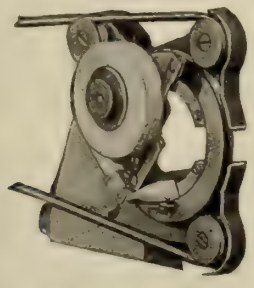
Owing to the fact that steel stampings are rapidly replacing small steel castings in a multitude of instances the demand for power presses of large capacity has been steadily increasing. To meet this demand, the press about to be described, has been placed on the market. It was built for the purpose of drawing pressed-steel axle housings for automobile trucks. These housings are drawn in two sections from steel ⅜in. thick, which sections are welded together. The press is of the tie-rod construction twin-driven and triple-geared. All the gears are made of steel, have machine dressed teeth, and operate at a ratio of 85 to 1. A series of toggles transmit the power from the main driving gears to the cutside slide or blank holder, and a dwell of 120 deg. is obtained. Power is transmitted to the blank holder from both sides of the press in order to keep the construction simple, and at the same time avoid torsional strains. The crankshaft that drives the inner slide also has a driving gear on each end. Power is furnished for adjusting the inner slide or plunger by a 15 h. p. motor mounted on the front of the crown. The press is driven by a 100 h. p. motor through a hand-operated friction clutch of the double-grip type. Some of the principal dimensions are as follows:—Distance from bed to inner slide (stroke down and adjustment up) is 59 in.; distance from bed to outer slide (stroke down and adjustment up) is 56 in.; stroke of inner slide is 28in.; stroke of outer slide is 20in.; area of blank holder face is 5ft. x 8ft., 6in.; and area of plunger face is 3ft. x 7ft., 3in.; while the weight of this press is about 300 tons. The press is manufactured by the E. W. Bliss Co. of Brooklyn, N. Y.

ANGLE BENDING MACHINE

The machine here shown, which has been placed on the market recently, is designed for bending angle iron into circular shape. It is provided with shears

Angle bending machine.

for cutting the angles to any desired length and special rolls permit of forming the stock to a true circle without defacing the angles. Rolls for any purpose may be used when desired. The forming rolls are made in two parts with a steel plate between for insertion of the leg of the angle. Circles may be formed with the flange either outside or inside. The machine is equipped with friction clutch and may be adapted to belt or motor drive. Frame is of semi-steel and rolls are made of forged and hardened tool steel. Machine may be supplied either with or without the cutting attachment. Floor space required is 4 x 5 ft., and weight is approximately 1,800 lbs. It is manufactured by the Excelsior Tool and Machine Co., East St. Louis, Ill.



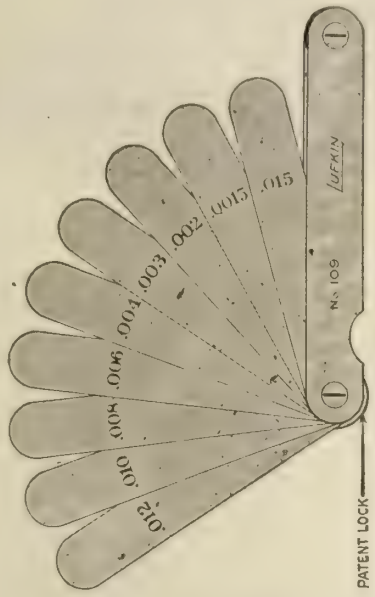
DUPLEX HAND MILLING MACHINE

The machine about to be described has been developed for rapidly slitting automobile piston rings of the step cut type, splitting babbitt-lined bearings for automobile crankshafts, milling slots and keyways and similar operations. The machine has a single-pulley drive from which power is applied by the medium of a friction clutch. On the driving pulley shaft is mounted a change pulley, from which power is applied to a pulley on the lower spindle by a belt. Spiral gears drive the upper and second spindle. These gears are hardened and run in oil. The number of teeth in these spiral gears differs by one for the more even distribution of wear. The spindles are made from high-carbon steel and run in bronze bearings.

The two spindle heads are adjustable and can be clamped in any position on the column without disturbing the gibs. The knee can be lowered or raised on the column, and as this member can be clamped in any position the locating of the work, with respect to the lower spindle, is done in this manner. In adjusting the set-up finally, the upper spindle head is adjusted relatively to the lower one. Then both heads are clamped to the column. Graduated dials are provided on all adjusting screws for securing accurate settings. The scale on the table can be moved toward or away from the column by means of a screw. The table is traversed past the spindles by operating a hand-feed lever. Electric drive can be applied if desired, by mounting a 1-½ h. p. motor on a bracket fastened to the base of the machine. The weight of the belt driven machine is about 900 pounds. The machine is manufactured by the Superior Machine and Engineering Co. of Detroit, Mich.

COIL TAPING MACHINE

The armature coil taping machine shown in the accompanying cut has been offered to the trade just recently. It is claimed to be a successful design, having a kickless self-feed attachment. It is easy to operate, the "pull" of the tape



Coil taping machine.

being taken off the operator to such an extent that the coil can almost be allowed to lay in the operator's hand while taping and permits him to increase or decrease tape at will while running. The device may be operated at approximately 500 r. p. m. Machine is durable and well constructed. It is being placed on the market by the P. E. Chapman Electrical Works, St. Louis, Mo.

THICKNESS GAUGE WITH LOCK

A very useful thickness gauge with a lock has recently been placed on the market. The lock provides a means by which the blades may be held in any position. It consists merely of a knurled head nut that clamps the leaves tightly together when it is turned a fraction of a revolution. The gauge is adapted for use of automobile mechanics and repair men. When making adjustments of tap-

Thickness gauge with lock.

pets on motors the proper leaf can be used at the full length of the tool, namely 5½in. The gauge is made in several styles. The No. 6 size carries six leaves having thickness of two, three, four, eight, ten and fifteen one-thousandths. The No. 9 has nine leaves from one and one half to fifteen one-thousandths. All the leaves are well protected when the gauge is closed. All the leaves are one half inch wide and three inches long. The removal and insertion of the leaves is easily accomplished. If two leaves are separated from the others and locked in position they may be used as the two limits that are permissible in the fit. The leaves are accurately ground to size which is marked on each. The gauge is manufactured by the Lufkin Rule Co., of Saginaw, Mich.

TUBE BENDING MACHINE

There has recently been developed and placed on the market a machine that bends No. 22 gauge 7/16in. diameter tubing to the shape of a tennis racket. To accomplish the complete bending, two separate operations are necessary. A lot of tubes are run through the first bending and then the machine is set up for the second operation. The preliminary shape is obtained by bending the tube around a form on the table by means of two arms, or cranks, keyed to two vertical oscillating shafts. The cranks are driven through worm gearing and a crank motion underneath the table. The mechanism is controlled by means of a clutch. There are rollers on the ends of the cranks which engage the tube and bend it around a large form. The normal cycle of steps in this operation is to bend and release the part and then stop the machine. The part is then removed and replaced with another straight tube. In the second operation the frame is closed by the rollers on the swinging arms, as the cranks are operated, one leg of the frame passing under the clip at the left of the table, the other riding over the top. It is necessary to bend the frame through a greater angle of curvature than is actually desired on the finished part, in order to overcome the spring and allow the tubing to set. The machine normally operates at an average rate of 600 bends per hour, with the speed of the driving shaft at 300 r. p. m. On normal production the machine is stopped after each bend but when an operator has become accustomed to handling the work and maximum production is desired, the clutch latch may be thrown out and the machine operated continuously. Under these latter conditions the capacity of the machine is increased to about 1000 bends per hour. The machine may be equipped to take care of a wide range of work which is somewhat similar in nature. The equipment is manufactured by the Davis-Bournonville Co. of Jersey City, N. J.

NEW EQUIPMENT

The Modern Machine Tool Co. of Jackson, Michigan, has taken over the stock and tools of the Sprague-Hayes Mfg. Co. and will make and sell the Quickgrip table vise formerly manufactured by the Hayes Co.

MEDIUM DUTY POWER HACK SAW

The light weight medium duty metal cutting saw shown in the accompanying cut has recently been placed on the market. It has all the features of other machines of the same make, and is especially adapted for fast and accurate cutting.

Power Hack Saw.

It is equipped with automatic lifting device that relieves the blade on the return stroke. Gravity feed is used in cutting. Saw is automatically stopped at finish of cut. Provision is made for quick and easy adjustment for wear. These machines are made by the Racine Tool and Machine Co., of Racine, Wis., and will be known to the trade as the "Racine" Junior.

New Engineering Bill

THERE IS A movement on foot to pass a bill in the Ontario Parliament which will make possible the incorporating of the professional engineers of the province. The present wording of this bill has some objectionable coercive features which should be remedied before its passing.

When presented to members of the legislature the other day, the general sentiment was in accord with the principle, viz., to give the engineering profession a recognized status, but luckily for the good of the province, objection was raised to the drastic clauses in the bill. After considerable discussion it was decided to let the matter stand until the committee consulted the engineers interested.

According to the present wording, any engineer not registered or licensed under the proposed association, and following out his profession, could be fined $100, $200 and $500, for the first, second, third and subsequent offences. In other words he must join up, pay a license fee, or drop out of the profession. Of course, these words are not bluntly presented, but that is what it amounts to. Here are how the clauses under discussion are worded.

The fines apply to a non-registered or non-licensed man who (a) practises as a professional engineer; (b) usurps the functions of a professional engineer; (c) uses verbally or otherwise the title of professional engineer, or of any words, name or designation that will lead to the belief that he is a professional engineer; (d) advertises himself as a professional engineer, and (e) acts in such a manner as to lead to the belief that he is authorized to fill the office of or to act as a professional engineer.

These are carefully worded statements, and yet, if allowed to go into force would work hardship on many men who have carried on in a small way for many years. Many of these are competent practical men who might not want to become members of the association or take out licenses, and therefore should not be coerced into such a step.

No one will question for a moment the need of organizing the engineering profession, for this should have been done years ago, but to start off in such a dictatory manner is not the way to get results. Granted that many men are practising as professional engineers who should be censured for so doing, still these are in the minority, and are soon found out.

The argument was raised that these clauses would safeguard the public, eliminating the fakers. All well and good, but before long we would have a worse condition on our hands, viz., a close corporation who could charge almost any fee it cared to. **By all means let us have an association**, but one governed by reasonable rules.

To define the term professional engineer, will prove in itself a problem, for there are the civil, electrical, mechanical, chemical, electric and mining fields. It will be some time yet before all these debatable points will be cleared up. In the meantime let the committee move cautiously, refusing to rush such a measure through until worded in such a way that it is fair and reasonable, not dictatory.

Have You a Convention Committee?

"HOW CAN we further reduce our expenses?" This question is being asked in every manufacturing plant in Canada, in fact all over the world. At the present time competition is keen, profits are small, and in many instances, firms are losing money instead of making it. The usual pruning of dead wood and flagrant extravagance has long since taken place. Now the task is to discover new channels for saving, and naturally these are not so easy to find, being underneath the surface.

The old idea of having the executive heads meet periodically to discuss ways and means of stopping leaks in efficiency is very good, but it does not go far enough. At the beginning everyone is full of enthusiasm and suggestions, but gradually these ideas taper off until the meetings fizzle out through lack of new suggestions.

The fault lies in the fact that the employees out in the shop have not been thoroughly sold on the necessity for saving. Cutting their wages is not the best way to save the situation. It shows a saving on the pay roll, but causes dissatisfaction, and quite often lowers production, the workman taking the stand that less money means less work. Before cutting wages, why not ask the men to form a "conservation committee." Tell them frankly the absolute need of such a body, and suggest to them that they pick only the best men available. Let them realize that this is the last stand before wage reduction. That you do not wish to reduce wages, but if something is not done at once, salaries will have to be cut. Appoint a similar committee in the office, then let them both work together.

This idea will prove successful, in fact has always done so where given a fair trial. One large company in the States says they saved $10,000 a year by adopting a policy such as we have outlined. Every industry will have its own peculiar problems, so that no hard and fast rule can be laid down. The main thing is to appoint the committees very carefully, realizing that this move means either profit, or continued loss.

Some of the sources of leak, which should be watched carefully are, personal telephone calls, needless waste of material both in shop and office, if production cards being used can be improved, and if more help is being carried than is necessary. The latter problem is always a difficult one to overcome, but with responsible and conscientious committees, they soon see that to make the jobs of all secure, including their own, they must view the problem from an unbiased standpoint. Many other suggestions could be made, but the idea is what counts. The sooner you start something along these lines the sooner your present losses will cease. The morale of the workers will also improve automatically, so you have everything to gain and nothing to lose.

Canada's greatest need today is creative and practical thinking by the individual. The agricultural and industrial world is composed of individuals.

Automobile Production Shows Decided Success

Iron and Steel Continue Firm—Steel Ingot Production Increases —Slight Advance in Price of Bars, Shapes and Plates in United States—Pig Iron Tapers Off—Small Tools and Supplies Active

BRITISH PIG IRON MAKES APPEARANCE

CANADIAN markets show practically no change over last week. Demand is keeping up, iron and steel being strongest of all. Prices are firm, and plates are moving at a good rate. These are being sold chiefly for tank work. Canadian representatives of American mills report good business in Canada at the present time.

Pig iron, is firm, but the quantity moving is not as large as a month ago. British pig iron has made its appearance on the Canadian market, and is selling more or less in Eastern territories. Toronto is beginning to investigate this new source of supply, and according to information received the price is about seventy five cents to a dollar cheaper per ton than the Canadian product.

Scrap and non-ferrous metals are a little stronger, copper being the most active. Yellow brass is weak being pratically a drug on the market.

Small tools and supplies are still active, the automobile trade helping this section considerably. Machine tools are moving, but not very rapidly.

Steel pipe is firm, and oils and waste are selling at a fairly good rate. Linseed oil has gone up slightly in price.

Automobile production in the States is very heavy. Several large makers are producing more cars to-day than at any other time in their history. The number of orders for freight cars is also increasing, nearly 10,000 having been ordered during the week. Structural steel lettings since April 1, have been heavy so that these three avenues of consumption have helped the steel situation considerably. In fact they are using up about 20 per cent. of the present steel output.

Outside of these three lines, conditions in the steel industry are less active, but the market is still firm because the mills are booked up for two months ahead at least.

Steel ingot production shows a further increase the rate being over 37,000,000 tons per year. Several additional furnaces have been blown in.

Steel prices continue to strengthen, and bars, shapes and plates are now quoted at $1.60, against $1.50, during the first part of May. Independent hoop, band, and strip makers have advanced their asking price from $2.00 to $2.25.

Connellsville coal has had a stiff advance during the past ten days. Eastern buying is responsible and the price for steam grade is now $4.00 to $4.50. Pig iron production is unchanged, and consumers are out of the market unless in pressing need.

Toronto

May 23

THE demand for iron and steel continues locally, but compared with last week, we can report no further improvement. In fact every section seems to be marking time, gathering in a fair amount of seasonal business only.

Iron and Steel.—The demand for iron and steel bars, plates, etc., is keeping up, and prices are firm, but not advanced, as several dealers have been expecting for some time past. Although plates cannot be termed a feature, they are selling strongest of all lines, 10 gauge and 12 gauge, being particularly active. One large representative of an American company reports very good business, and says that May will be without question a big improvement over any other month in 1922 so far as he is concerned. The demand in his case is general, orders coming from a very scattered territory.

Gossip on the market states that American mills are going to raise the quantity differential. In other words, refuse orders at straight mill prices on less than five ton lots. At present there is a special charge on small orders of one ton or less, but the representative of one large American firm, states there is nothing to the rumor. What has occurred is this:—

Certain mills will not accept orders on less than 5 ton lots from new customers, but continue to serve their regular consumers as before. The only difficulty when ordering small quantities direct from the mills is to get quick delivery.

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron:—This market is firm, although buying is not as heavy as it was a month ago. A new factor has entered into the situation, viz, British competition. This so far is chiefly confined to Montreal and Eastern territories, but Toronto is beginning to be interested. One large user of pig iron, told Canadian Machinery that he was at present in touch with a British firm and would be able to give us something definite regarding comparison of prices in a few days. From varied sources we find that about 75 cents lower than the Canadian figure seems to be the average. The Toronto price of Canadian No. 1 iron is still $29.15.

Scrap Metals:—Scrap copper is brighter than it has been for some time past. A number of sales are reported and prices are firm. Heavy melting steam has also improved and tonnages have been booked around $12.50 to $13.00 Hamilton. The cast iron market is both active and firm. Dealers however refuse to stock up further, so that the quantity of sales is not as large as the strength of market would warrant under normal conditions. Stove plate is scarce and hard to get, therefore the price is nominal. Following are quotations on several lines.

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Non-Ferrous Metals:—This market is firmer, although the demand has not increased. Consumers are still a little shy about placing orders, but dealers on the other hand are holding to their quotations. The majority of merchants have large stocks on hand, which they are holding on to until the market becomes still firmer, then they will unload. Until that time, they refuse to stock up further and things are somewhat quiet so far as buying and selling is concerned.

Some metals are stronger in tone than others. Copper is best of all, with yellow brass the lowest. In fact the latter is a drug on the market. Local quotations follow:—

Copper, light, per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools:—This section is simply holding its own. There is no change, and although several good prospects are on top, none of these have reached the closing point. One dealer, who felt sure of a certain order, wired to his principals for best delivery, and although having received special concessions, he still cannot close the deal as the prospect has cooled off in the meantime. This incident could be repeated many times over and goes to show the state of the market. Prices are fairly firm, but orders received are for one machine only.

Small Tools and Supplies:—There has been no change over the week. The demand is satisfactory and as good as can be expected considering conditions. Prices remain the same, and the automobile industry is the chief channel of consumption. The class of goods moving is general.

Steel Pipe:—This section of the market is decidedly firm. There is some talk of an advance in the States but so far nothing has occurred. Of course if prices go up on the other side, a similar advance would take place locally. Speaking to one large purchaser of this material, we find that he has ordered well ahead in order to play safe and ensure prompt delivery. He believes prices may advance shortly and refuses to take chances.

Oils and Waste:—Both these lines are moving at the same rate as last week. There is only one change in price, linseed oil having advanced slightly to $1.15 against $1.10. Following are local quotations.

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	0 33
Black oil, per gal.	0 17½
Cylinder oil, Capital	0 61½
Petroleum fuel oil, bbls., net	10 40
Pure turp., single bbls. gal.	1 35

Coal:—The first shipment of British coal is on its way to an American port. This move is creating considerable interest, and if the present American prices continue to advance in like proportion to what it has been doing recently, it will mean that British coal will be able to be sold on a competitive basis.

Montreal

May 23

A LITTLE better tone is in evidence on the local market. Business in practically every department shows a slight improvement, and building activities are still in the limelight. Most of the larger jobs are well under way or are practically finished. There is, however, an increasing number of residential and retail commercial construction contracts being let. This has been responsible for the increased business in nails, spikes and all kinds of building hardware. To a certain extent it has also been the cause of the increased demand for galvanized and blue annealed sheets, and small lots of structural steel. No changes in prices have been announced locally in steel products. Pig iron sales have dropped off still further, and the non-ferrous metal market is very quiet, although there is an undercurrent of strength to all quotations.

Iron and Steel.—The demand for steel products locally, and throughout the province, has shown a slight improvement during the week. The most activity is shown in galvanized sheets. British sources are supplying practically all the material being offered locally. Deliveries have been very good from the mills owing to the increased ocean tonnage available. Those jobbers, who were more or less conservative in their early booking for shipment by the all water route, have found it is difficult to keep any of this material in stock.

Blue annealed sheets are also rather active. Prices have not changed in the last week. Structural sections are moving in small lots but the total tonnage is not great, although in advance of the amount moved during the fall and winter months. Merchant bars are fairly active, a demand for small lots coming from all parts of the province. Spikes, wire nails, reinforcing rods, and a number of miscellaneous products are moving well. Prices in these lines are firm. Sheets are still in poor demand, but on the whole there is a very optimistic spirit among the jobbers and consumers. Local quotations are:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Subsequent to the last advance in pig iron there was a very healthy buying period. In two weeks it had spent itself and interest in this market is now very slight. Foundries are pretty well covered and they are not melting a large tonnage. The present quotation of No. 1 iron is firm at $31.80. A new factor has been introduced lately in the form of British iron on the local market, which has been quoted a little below the price on the Canadian product. Quite a few fifty-ton lots of this Summerlee iron have been placed locally, and the price is understood to be from seventy-five cents to a dollar a ton cheaper than the Canadian pig. The feature is too new and has not assumed large enough proportions for one to judge what its effect will be, but it may have the effect of making it difficult for Canadian producers to sell their iron to local consumers, also to those within quite a radius of Montreal.

Machine Tools.—Sales of machine tools are not yet up to expectations. Most of the large shops, which really form the best market for the local jobbers in these lines, are not working to more than fifty per cent. capacity, and some not even that. Thus, it is impossible to interest them in new tools. The railways are not showing any desire to come into the market. They are not moving a large volume of freight, and the shops have no difficulty in taking care of the necessary maintenance. Thus, they too are eliminated. The small manufacturing establishments, together with the jobbing and contract shops, present the only outlet for machine tools. These plants are buying a little new equipment but it consists of small-sized machines in lots of one only. Wood-working machinery is moving a little better than iron-working tools, but business is not active even in these lines. Prices remain fairly steady.

Small Tools and Supplies.—The demand for small tools continues to be pretty good. There is a gradual improvement in the demand, local repair shops are fairly busy, as the opening of navigation has brought a fair volume of marine repair work.

Non-Ferrous Metals.—Very little business is offering in this market locally. Quotations are firm owing to export, etc. Copper, tin and lead appear to be very firm, but this feature does not stimulate buying. Local quotations are:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 50
Lead	6 75
Spelter	7 50
Antimony	6 50
Aluminum	23 00

Scrap Metals.—A very small volume of business is offering in scrap. Foundries have not come into the market to any extent, and owing to outside increased demand, local dealers advanced quotations, the result being that business that might have been done at the original figures has been lost, for the time being. Following is a list of quotations:

Copper, light per 100 lbs.	9 50
Copper, crucible	12 50
Copper, heavy	12 50
Copper wire	12 50
No. 1 composition	9 50
New brass cuttings	7 00
Red brass turnings	8 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	12 50
Boiler plate, per gross ton	8 50
Heavy melting steel	10 00
Axles (wrought iron)	9 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	22 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	18 00
Cast boring	3 00

Pittsburg

May 23

FREIGHT cars ordered in the past week total nearly 10,000, making about 75,000 since the first of the year, against less than 30,000 during 1921, and an average of 150,000 a year in the ten years 1904 to 1913 inclusive. The present rate of buying is as heavy as could be expected. It should be remembered, however, that freight cars cannot furn-

ish as large an outlet for the steel industry as used to be the case, on account of steel making capacity having been so greatly increased. The present capacity is about 150 per cent. greater than that of 1904, and 50 per cent. above that of 1913, while no heavier freight car buying than in those years can be expected.

Structural steel lettings have been heavy since April 1, equalling approximately the fabricating shop capacity, which is 180,000 to 200,000 net tons a month. Lettings in the first three months of the year equalled 53 per cent. of capacity, while in 1921 it was 35 per cent. Automobile production is very heavy. Studebaker, Dodge, Maxwell, Ford and Chevrolet are producing more cars than ever in their history. Production in April, as reported by the Department of Commerce, with reports from a few small companies lacking, was 196,512 passenger cars, and 21,944 trucks, against 81,638 passenger cars, and 9,204 trucks, in January. Production this month is running a trifle heavier still.

These three important lines of consumption, extremely stagnant in 1921, are the largest outlets for steel at the present time. They represent at the present rate about 500,000 gross tons a month of finished rolled steel, apart from iron castings, etc., which is equal to a rate of 6,000,000 gross tons a year. Total capacity in finished rolled steel is about 40,000,000 gross tons, while the present rate of production is 28,000,000 to 29,000,000 tons, so that these three industries account for a trifle more than 20 per cent. of the present steel output.

Steel Market.—This market in general, outside of the three lines just mentioned, is decidedly less active than in March and April. The lessening in activity has not weakened the situation, because mills are well sold up for a couple of months or more and do not need to secure much of any additional business for nearby deliveries to enable them to maintain operations. General buyers are moderately well covered, but apparently a few would like to have more steel, this being evidenced by some anxious inquiry in the market, against which some of the mills, probably the great majority, are endeavoring to secure delivery premiums.

In other words, the steel market presents an appearance of great strength, yet there is some room for doubt whether this strength will really continue. The lines of consumption outside of freight car building, structural steel construction, automobile and truck manufacture, do not present the appearance of actually consuming 75 per cent. of the steel now being produced. It would look rather as though some buyers and distributors have been replenishing stocks and will not require as heavy deliveries later on unless the ultimate consumption increases further.

The buying thus far is readily explained, for stocks were at an extremely low ebb at the beginning of the year, and fears regarding the coal strike of April 1 caused buying before that date, while when the strike proved to be somewhat bigger than was expected, on account of some non-union regions striking in addition to the regular union fields, a further stimulus to steel buying was given.

Steel Ingots.—Last December steel ingot production was at a rate slightly under 20,000,000 tons a year, there having been a decrease from the October-November rate. By March 1, the rate was up to about 30,000,000 tons, and the end of March saw approximately a 35,000,000-ton rate, the average during March being 32,500,000 tons. In April, on account of the coal strike, the increase was almost interrupted, but as reported a week ago the April production was at about 36,500,000 tons a year. There has been a further increase, and the rate is now about 37,000,000 tons.

Some of the steel companies, those largely dependent upon coal regions where there are strikes, have had difficulty in maintaining supplies, but they are succeeding. Coal and coke have been purchased in different fields, but an extra freight haul is involved, adding to the expense. The steel industry had large stocks of coal April 1, and these have been drawn upon to quite an extent, but they have still fairly large stocks.

The Carnegie Steel Company resumed steel making at the Mingo works the beginning of last week after an interval of more than a month, while late in the week production was resumed at the Farrell works after a long idleness. The Carnegie Company is now operating 35 blast furnaces, against 34 on April 1. The Youngstown Sheet & Tube Company has blown in a fourth furnace, and there is also some increase in the Chicago district.

Steel prices continue to grow stronger. Some of the independents have advanced asking prices, while other producers are more conservative, and restrict their bookings to the most desirable business rather than advance prices. In bars, shapes and plates, however, the market in general seems to be quotable at 1.60c, against 1.50c ruling in April, and the fore part of May, and about 1.35c late in February. Sheets are regularly 2.40c for blue annealed, 3.15c for black, 4.15c for galvanized and 4.50c for automobile sheets. A half dozen or so independents are quoting $5 to $7 a ton higher and offer early deliveries at their quotations. Independent hoop, band and strip makers have advanced their asking price from 2.00c to 2.25c.

Pig Iron, Coal and Coke.—Connellsville coal has had a stiff advance in the past ten days, chiefly on account of eastern buying, and is $4.00 to $4.50 for steam grade. Connellsville furnace coke, which has presented a very narrow market, as furnaces are buying only in exceptional cases, is a shade easier at $6.25 to $6.50. Foundry coke is unchanged at $6.75, with the turnover rather light.

Merchant furnace production of pig iron is at about the same rate as for several weeks past, with furnaces unable to increase output and with the current output well absorbed on old sales, the result being that sales would only be made at prices that are very high compared with those ruling in March, the quotable market being about $26 for Bessemer, $25 for basic and $24 for foundry, f.o.b. valley furnaces. Consumers are out of the market unless in pressing need of some particular lot, and the market in the past fortnight has seen the lightest turnover for a very long time.

IMPROVED FURNACE FOR CAST IRON

In every foundry throughout the world the furnace is accepted as the standard to be used on account of its low first cost, its economy and its convenience. Such drawbacks as it possesses are not of serious importance in ordinary foundries, but they do become troublesome when high grade work is undertaken. A British firm has therefore devised a special type of cupola furnace for the production of the highest grade of castings. The chief peculiarity of this furnace lies in the oil firing of the receiver. The molten metal collects in the hearth of the receiver and the power of the oil flames can be regulated to suit the quantity of metal concerned. In this way any quantity of metal can be maintained for a long time at the correct casting temperature. The approximate consumption of oil is at the rate of three gallons per ton of metal.

Model making as a hobby would appear to be on the increase. The educational advantages, and the aptitude which many people find they possess for building these small models have proved sufficient to attract people in many walks of life. For this hobby the use of treadle lathes and small hand or power operated machines for drilling, surfacing, etc., is a more or less urgent necessity. Another class of user for which these small machines are made is the man with a motor car who is far away from any commercial repair shop and is therefore dependent on the work he is able to perform in his own garage for minor adjustments and repairs. A steadily increasing field for the small lathe has been found amongst this class of user especially. The precision lathe, however, is primarily a works instrument. It costs a good deal more than the machines capable of making the small parts required in a model and its operation often requires on the part of the operator a very high degree of skill and experience in order to achieve the best results. Amateurs rarely achieve these qualities but in some cases, where men have made a hobby of such fine work as clockwork apparatus, they have often found it worth while to use the highly accurate machine tool.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

News From the Industrial Field

The Georgetown Arena Co., Georgetown, Ont., are contemplating the erection of an arena.

Reynolds Ltd., is the name of a newly organized company in Montreal. The capitalization is $50,000 and this construction company was formerly controlled by Mr. G. B. Reynolds of Montreal.

Sealed bulk and separate tenders addressed to A. Love, secretary-treasurer of High School Board, **Aurora, Ont.**, will be received until June 6, for all trades in the erection of an addition to the present high school.

The Pangborn Corporation sand blast specialists of Hagerstown, Ind., will have a representative line of sand blast equipment on exhibition at the **Foundrymen's** Convention to be held in Rochester, N. Y., on June 5 to 9.

Mr. Thos. Reid of the Hamilton Facing Mills, Hamilton, Ont., reports business as being exceptionally brisk. Car wheels and pipe foundries are particularly active, these branches alone, ordering considerable quantities of material from the facing mills.

Niagara Falls, Ont.—Some important changes will be made to the bridges here. Present plans call for a complete new structure between the present cantilever bridge and the one used by the G. T. R. and pedestrians. The contract for the latter calls for its completion within two years. The lower bridge will also be greatly extended.

Hamilton, Ont.—G. A. R. Emery, Canadian Trade Commissioner, will leave shortly for Shanghai, China. Several local manufacturers have interviewed Mr. Emery, and stated their desire to increase their export trade. Manufacturers of steel goods, tinware, canned goods, roofing material, wire fencing, farm implements and brushes are especially interested.

Following are some new incorporations, with their head offices: E. W. Herring, Ltd., capital, $49,500, head office at Montreal, to carry on general contracting business. Fibre Asphalt Products, Ltd., capital $500,000, head office Toronto, dealing with paving materials and machinery. W. R. Hughes Co. of Canada, capital $50,000, head office at Toronto, to manufacture and deal in paints, varnishes, oils, etc.

McGinnis & O'Connor, highway engineers and contractors, Kingston, Ont., have been awarded the construction of some seven miles of highway near the town of Gananoque. One mile of the work is on the western, or Kingston side of the town, and the rest on the eastern or Brockville side. Work will be commenced at once.

Baker Brook, N. B.—Fraser Co. whose shingle mill was recently destroyed by fire will rebuild at once.

Brockville, Ont.—A rolling mill for E. F. Phillips Electrical Works, Montreal, will be erected in the near future. Tenders closed on this work May 22nd.

The Ford Motor Co., Calgary, Alta., is contemplating the erection of a warehouse and salesroom at a cost of $150,000.

St. Williams, Ont.—McCall Bros. Woodworking plant has been destroyed by fire. The loss is approximately $70,000.

Lindsay, Ont.—The shingle mill, owned by Joseph Hadley, of Burnt River has been destroyed by fire. The loss is a heavy one, and a number have been thrown out of employment.

Westminster Junction, B. C.—Tenders will be received up to June 10, by Hon. Dr. W. H. Sutherland, minister of public works for the erection of a steel highway bridge. The plans are with the governmental agent at Vancouver, district engineer at New Westminster, and with the dept. of public works, Victoria. Accepted cheque is required.

According to official figures, the fire losses in Canada during the week ending April 5, are estimated at $735,800, compared with $1,617,100 the previous week. Fire losses in Canada in March totalled $4,331,750, compared with $4,062,400 in February and $2,112,200 in March last year. This exceptionally high figure is due to the loss of Montreal City Hall and of the church at St. Anne de Beaupre, amounting to about $1,000,000 and $1,200,000 respectively.

The Thomas D. Watson Co., Kingston, Ont., has at present under construction the first two buildings of a factory which when finally completed will consist of five buildings all of reinforced concrete or steel. The foundry and machine shops are the units now being erected, and a twelve ton cupola will form part of the foundry equipment. The foundry will be 110ft. by 70ft., and the machine shop 170ft. by 70ft. The other buildings will be started as soon as possible.

Grand Prairie, Alta.—A flour mill and elevator will be erected shortly by Shaver and Taylor, at a cost of $30,000.

Deschambeault, Que.—Tenders are requested for alterations to wharf to cost about $70,000 for Dominion Government. J. B. St. Laurent, chief engineer, department of public works, Ottawa, is the man to write to. Other plans being prepared, and handled by the same office are repairs to wharf at Grondines, Que.; wharf repairs at St. Antonine de Tilly, Que., the latter to cost $10,000.

The Canadian Pacific Railway Co. plans to spend $50,000 in building an overhead crossing over the Grand Trunk tracks immediately west of Kingston.

C. C. Bradley president C. C. Bradley Co., Syracuse, N. Y., is enjoying his annual two weeks' outing with the Triton Club, Quebec. This means that the trout season is now open.

J. V. Gray Construction Co., general contractors, 541 Queen St. E., Toronto, and 36 London St. W., Windsor, have opened new offices in the Bank of Toronto Chambers, London, Ont.

Medicine Hat, Alta.—Work has started on the construction of a 280-ton mechanical coaling plant for the C. P. R. G. E. Hughes, of Calgary, is the contractor in charge.

The Shawinigan Water & Power Co. Shawinigan Falls, Que., contemplate the installation of an electric lighting system in the town of Riviere A Pierre, Que., in the near future.

The Railway Roller Bearing Co., Syracuse, N. Y., has been re-organizing. Mr. Stacey, former manager withdraws and his place is taken by J. C. R. Bell, formerly with the Gurney Ball Bearing Co., Jamestown, N. Y.

Chipman & Power, consulting and supervising engineers, Toronto, have been retained by the town of Oakville, Ont., to make a report on a suitable auxiliary for operating the water pumps in the event of a tie-up in Niagara power. According to present plans, a capacity of approximately 300 h.p. will be required, which will be a single unit engine, either gasoline or Diesel type.

Ottawa, Ont.—The contract for the excavation of the new Nepean High School, on the corner of Broadway and Princess Avenues has been let to Bate McMahon and company by the High School Board. The work is to be completed by the first week in June. Next week the board will probably call for tenders for the foundation and structural work.

Montreal, Que.—The firm of Messrs. Rochester, Rhind and Fair have been organized for the purpose of marketing and installing the radio apparatus that is now being manufactured by the Marconi Wireless Telegraph Co. of Canada. All three men are graduates of McGill University and have specialized in electricity. They have fitted up a demonstrating set at their headquarters, 15 St. Mark St., where the working of same is fully explained, also the functioning. The firm are making it their business not only to sell, but to install all sets that they dispose of. In this feature they are without competitors at present locally.

Toronto, Ont.—The value of building permits for April totalled $3,555,325, against $2,617,269 for April, 1921.

Preston, Ont.—The Hurlbut Shoe Co. is building an addition to its plant, and when this is completed the present capacity will be doubled.

Manager Moore of the International Nickle Co., Port Colborne, Ont., states that another furnace has been put in operation in order to meet improved conditions. Fresh orders are being received daily.

Toronto, Ont. — Appropriations of $850,000 for carrying on the work of improving the Toronto harbor, also $50,000 for work on the breakwater at Toronto Island, has been voted on at Ottawa.

Windsor, Ont.—Building records for April show a substantial increase over the corresponding month of last year. The total value is now $444,495 against $292,485.

The English and Welsh Railways have announced important reductions in frieght rates. A cut of 50 per cent. has been made in collection and delivery charges. Rates are also reduced on iron and steel, brick, and some other building materials.

According to figures issued by the Labor Department, the volume of employment shows considerable revival during April. At the close of April, some temporary shut downs in railway shops caused reductions in employment, but other increases more than offset this trouble.

Canada's newsprint capacity will soon be increased when the two new mills now in course of erection are completed. The capacity will then be 1,032,600 tons annually, or approximately 50 per cent. of the total newsprint consumption on the American continent. During the last year, seven new machines with a total rated capacity of 558 tons daily of newsprint has been brought into operation.

London, Ont.—Sealed tenders will be received at the office of John M. Moore & Co., architects, up till noon May 31 for the construction of a steel and reinforced concrete bridge over the north branch of the River Thames. Plans can be seen either at the aforementioned office, or at the office of R. E. W. Hagart, consulting engineer, Temple Building, Toronto.

According to figures issued by the Dominion Bureau of Statistics, Canada's exports to Japan for 1921 amounted to $10,094,243, an increase over 1920 of $2,800,000. This means that Japan was Canada's eighth best customer as compared with ranking sixteenth in 1920 and thirteenth in 1919. On the other hand, Japan sold to Canada last year goods amounting in value to $7,923,450, as compared with purchases of $13,859,732 in 1920 and $12,697,297 in 1919. Japan was our ninth largest supplier of imported goods during 1921.

The National Silk Dyeing Co., of Patterson, N. J., have purchased 13 acres of land at Drummondville, Que. They will proceed with the erection of a Canadian plant immediately.

According to latest reports the Canadian Government will send an exhibition train to France this year. An item of $50,000 to cover the cost has been passed, and it is stated that both agricultural and industrial exhibits will be sent.

Calgary, Alta.—City commissioners have recommended the purchase of a Lincoln arc welding outfit at a price of $4,092 f.o.b. Calgary, from the Electrical Engineers, Ltd., Calgary. Lee Drumheller of the same city has announced that steps have been taken by the Drumheller Land Co., to erect a new generator to replace the one lost at the Callie mine fire recently.

Among the leading articles that will appear in June issues of Canadian Machinery are the following: June 1, Punch Presses and What They can Accomplish; June 8, Machine Shop Problems of Interest; June 15, Belting—Its Uses and Proper Care; June 22, Reducing Costs by Means of the Planer; June 29, Value of Keeping a Product Clean.

Owen Sound, Ont.—The city council have authorized the issuing of debentures up to $200,000, for the work necessary in the building of the new technical department at the Collegiate Institute. Present plans provide for a building about 375 feet in length, 48 feet in width, and 35 feet high. It will be erected west of the present building and joined to it, physical and chemical laboratories, technical and home making classrooms, domestic science, gymnasium, woodworking shops, forge shops and principal's office all on the main floor. On the second floor will be a draughting room, typewriter and commercial rooms, two part-time classrooms, a lady teachers' room and a girls' restroom. Rooms for dressmaking and millinery are also provided.

ELECT OFFICERS FOR COMING SEASON

The following officers were elected at the annual meeting of the Peterborough branch of the Engineering Institute of Canada. Hon. Chairman P. L. Allison, Canadian General Electric Co.; Chairman P. P. Westbye, general manager and chief engineer, William Hamilton Co.; Vice-chairman, R. L. Dobbin, water works superintendent, Utilities Commission; Secretary, R. C. Flitton, Wm. Hamilton Co.; Treasurer, A. B. Gates, Canadian General Electric Co.; Executive committee, H. O. Fisk, manager Electric Department, Utilities Commission; E. R. Shirley, Can. Gen. Electric Co.; W. M. Cruthers, Can. Gen. Electric Co.; A. L. Killaly, Supt. Trent Canal; A. A. Richardson, Res. Engineer Utilities Commission; B. L. Barns, Can. Gen. Electric Co.

The Canadian Pacific Railway Co. have announced a reduction in tourist fares which will save money to those attending the Good Roads Association at Victoria, B. C., June 13 to 17. A rate of $110.65 has been set from Toronto to Victoria and return, limited to Oct. 31.

Ottawa, Ont.—The steel tow barge Brighton has been recently rebuilt and converted into a wrecking lighter by the Canada Steamship Lines. A Browning hoist and powerful double acting pulling machine have been installed. She, with the tug H. F. Bronson, will form the company's wrecking fleet and will be stationed at Prescott prepared for future salvage work, as necessary.

The Dominion Bridge Co., Montreal, have the contract for installing an 80 foot travelling crane in the plant of the Lackawanna Tube Co., Welland. This plant is being equipped to produce boiler tubing, the first of its kind in Canada. It is reported that its output for the first year of operation is practically sold. Billets for this mill will be made in a rolling mill which is now preparing to locate in Welland.

It is stated that the Lackawanna Tube Co. is in some respects a subsidiary of the Lackawanna Steel Co., which recently formed an amalgamation with the Bethlehem Steel Co.

The Volta Mfg. Co., Welland, Ont., have perfected an electric soldering furnace, which has just come through a satisfactory test in a radiator plant. In a report on this test it is pointed out that the consumption is only about 840 watts per hour, and that 1,200 degrees are required to heat the iron. It takes from ½ to ¾ of an hour to heat up to the required temperature for 1½" coppers and 3 minutes to heat a pair of coppers after the furnace is hot. Dressing and cleaning of coppers are no small items and with an electric furnace this is done in one-half the time required by gas.

Working conditions in the vicinity of the furnace are greatly improved, since the heat is almost entirely eliminated and there are no noxious gases. The cost is also slightly in favor of the electric furnace and the plant in question is making complete installation of 12 furnaces.

BOOKLETS

The Canadian Engineering Standards Association has just issued a book of standard specifications for steel railway bridges. This treatise is intended to give to the bridge designer, detailers and manufacturer, guidance along definite lines that will lead to uniformity in the provisions to be made for strength and utility. The various clauses have been prepared without any intention of limiting the engineer's choice as to the type of bridge, and it is believed that no unnecessary restriction has been placed on the designer as regards details of construction. This edition is new and considerably revised and superseded that issued in 1920.

LOCOMOTIVE INDUSTRY IN GREAT BRITAIN SHOWS DECIDED IMPROVEMENT

SPEAKING on the locomotive industry in Great Britain, F. W. Field, H. M. trade commissioner at Toronto, remarked to Canadian Machinery that the average British builder has in the past devoted himself to supplying certain well-defined markets, a policy which has from many points of view stood him in good stead in the post-war period when costs were high and most foreign buyers were unable to purchase, and the constant fluctuations of the exchanges made fair competition between nation and nation practically an impossibility. The Indian Government, the private railways of India, the Crown Colonies, and, to some extent, the Dominions, have given him a measure of welcome assistance and have enabled him to weather the financial storm.

The recent general improvement has, however, produced a great change, and practically every builder in the country is actively attacking the whole of the South American Continent, European countries outside France, Germany and Italy, and practically the whole of Asia. Technical and commercial agents have been established, directors and managers are making frequent tours, the special requirements of these markets are being studied, and designs to suit the expressed tastes of the authorities concerned are being submitted whether tenders are invited or not.

Recently quite a number of orders have been secured in this way. Russian, Chinese, and small Argentine orders are now on the books and it is confidently expected that at an early date Roumanian and Bulgarian orders will be forthcoming. The policy of building their own stock, which is now observed by the home railway companies, has left the private builders free to devote the whole of their attention to overseas work and has resulted in their being able to give good delivery at reasonable prices, and of the detailed construction required by the foreign buyer.

The results of the operation of these new factors are making themselves apparent at the present moment. It is rumoured, on good authority that the State Railway Department of the Roumanian government is about to place extensive orders for main line locomotives with British builders to the amount of 344.

The price quoted for each engine is £12,000. Negotiations are also known to be proceeding with some prospect of success between a British group and the Roumanian railway authorities for the reconstruction and management of the Roumanian repair shops. Active competition has been put up for the locomotives required for The Sorocabana Railway Co. of Brazil, the Patagonian Railway, the Buenos Aires Docks and the Chilean State Railways, and although the results are not yet known, some of the builders feel that they are likely to secure some of these orders.

An order for 45 locomotives for the New Zealand Railways has recently been secured by the North British Locomotive Co., which has also been receiving several small orders from other quarters, and though for these reasons its order books are fairly full, it is ready and able to entertain further enquiries for later delivery.

The two latest additions to the ranks of British locomotive builders, viz., Sir W. G. Armstrong, Whitworth & Co., and Wm. Beardmore & Co., have been kept extremely busy since converting their works for this purpose and have executed the orders so far received with credit to themselves and British prestige. Excellent reports have been received of the working power of these engines.

"It may be stated in brief," concluded Mr. Field, "that the past month has brought a very favorable turn in the tide of locomotive affairs, and this industry promises to enjoy in the near future a period of prosperity."

INDUSTRIAL

Condon's Ltd., have begun construction of a store and office building on the site of their old building, Barrington Street, Halifax, N. S., recently badly damaged by fire.

Tenders for the erection of a new school building at North Sydney, N. S., are to be in this week and the town council has decided that local labor must be employed except where special technical qualifications cannot be filled by local men. This is with the idea of relieving the local unemployment situation as far as possible.

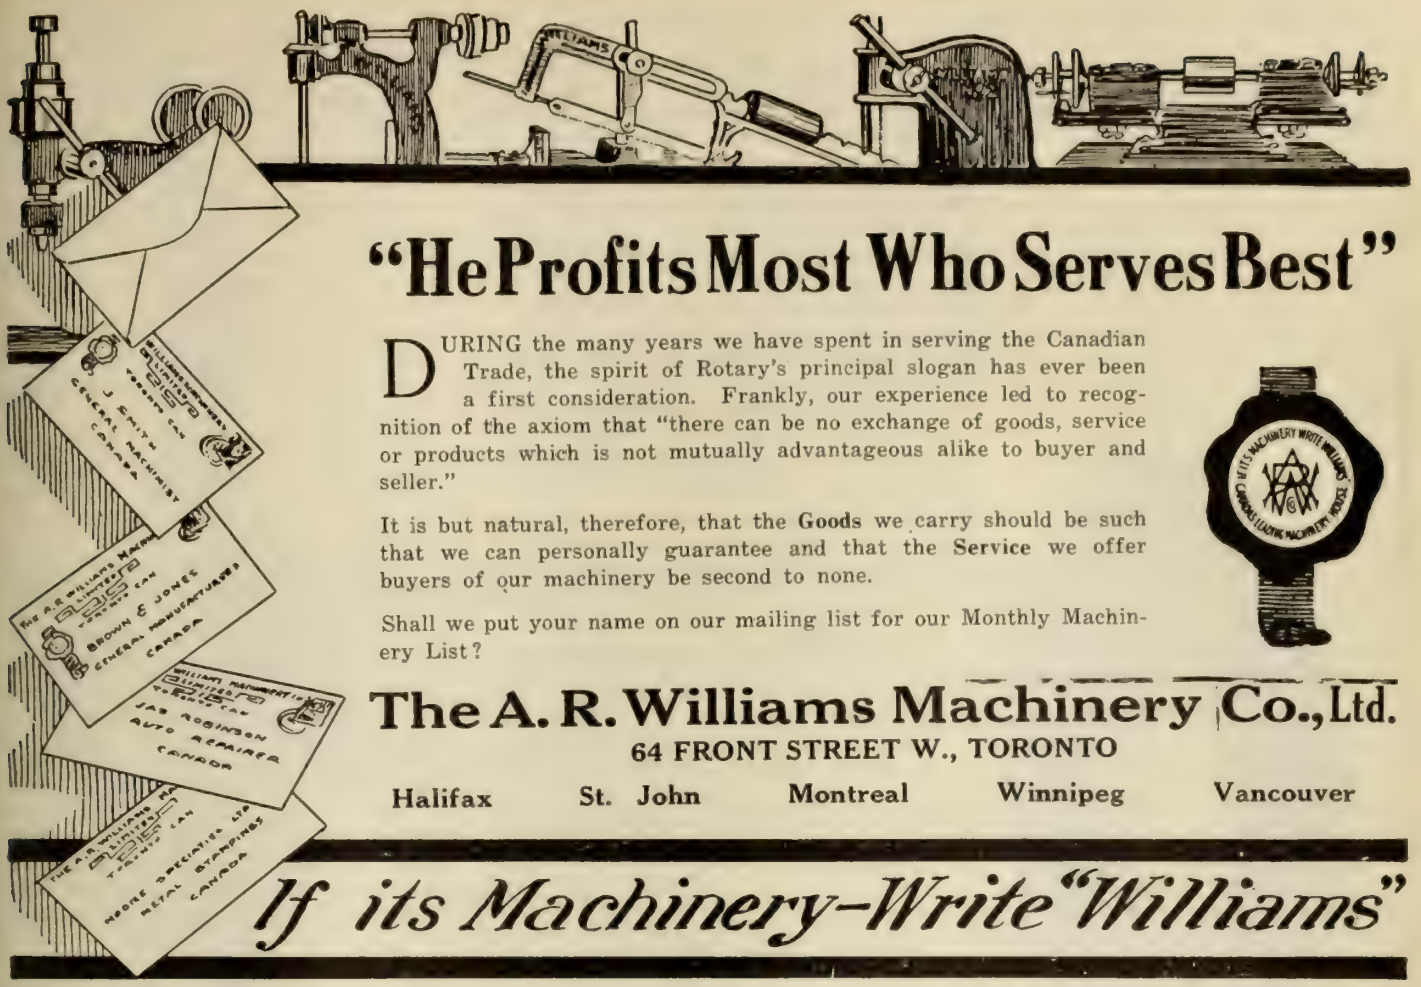
The Ford-Smith Machine Co., Hamilton, Ont., are at present working on some interesting machines, which are special in character. They are building a machine to make metal lath, also several roll-edge mattress machines, which are made under what is known as the Droll patent. The latter mentioned are for Canadian export trade, and the Ford-Smith Co., are going to make all these machines in Canada.

The group of buildings erected on the Halifax Commons for temporary housing by the relief commission after the great explosion of 1917 has been purchased by a salvage company which is to raze the buildings, sell materials therefrom and erect some dwellings in other parts of the city. The group of relief buildings on the citadel has been purchased for removal by Mr. Patrick and he has men at work on some of them that are now unoccupied, dismantling them in preparation for razing.

The Ford-Smith Machine Co., Hamilton, Ont., are now handling a self-contained grinder and buffer complete with motor, made by the Marathon Electric Mfg., Co., Wausan, Wis,. U. S. A. This grinder is equipped with a ¼ h. p. single phase motor, totally enclosed. It is an alternating current motor for 110 or 220 volt, 60 cycle, service, but a direct current motor can be supplied at slightly added cost.

A 6 x ½ in. abrasive wheel, and 6 x ⅜ in. cotton buff wheel forms part of the equipment, and the machine has a switch in the base. The grinder is fitted with 10 ft. of cord and standard plug ready to attach to any light or power circuit.

The firm of Kelvin, Bottomley & Baird, Glasgow, Scotland, which was founded about fifty years ago by the late Lord Kelvin for the manufacture and sale of navigational instruments, has just established a branch company in Montreal under the name of Kelvin, Bottomley & Baird (Canada) Ltd. The Montreal company will keep a large stock of instruments, and they have secured as manager, Captain Alexander Andrew, who is an expert compass adjuster and navigator, who also carries an Extra Master's Ticket. He is located at the company's offices, No. 111 Commissioners street, Montreal, and will always be at the service of vessels coming to the port. Drummond, McCall & Co., have until the present acted as agents for Kelvin, Bottomley & Baird, and they will continue to be intimately connected with the new company. Mr. J. T. McCall will be president, and associated with him are Mr. M. B. Field of the Glasgow Company, and Mr. Wilfred O. White of Boston.



W. H. Coverdale has been appointed president of the Canada Steamship Lines. He has already left on a personal inspection of the company's properties to familiarize himself with all the details of the company's operations and various activities.

Mr. Coverdale is partner of Coverdale and Colpitts, consulting engineers, but now intends to spend a large part of his time in Montreal during the season of navigation. He is a former Canadian, is deeply interested in the development of the Dominion's resources, and believes that one of the most effective ways of attaining that end is the provision of efficient means of transportation, both by land and water.

He is also chairman of the board of directors of the Pittsburg and West Virginia Railway company and of the Pittsburg Terminal Railway and Coal company, a director and member of the executive committee of the Gulf State Steel company, of Chicago and Eastern Illinois Railway company, and of Gulf, Mobile and Northern Railway company

---

For plane surface grinding, single grain, or what are known as "straight grain" wheels are used, because such wheels are more open grained than combination wheels, and consequently there is more room between the grains for the removal of chips.

"He Profits Most Who Serves Best"

DURING the many years we have spent in serving the Canadian Trade, the spirit of Rotary's principal slogan has ever been a first consideration. Frankly, our experience led to recognition of the axiom that "there can be no exchange of goods, service or products which is not mutually advantageous alike to buyer and seller."

It is but natural, therefore, that the **Goods** we carry should be such that we can personally guarantee and that the **Service** we offer buyers of our machinery be second to none.

Shall we put your name on our mailing list for our Monthly Machinery List?

DESIRE INFORMATION

This is a period when everybody is looking for new channels through which to dispose of their goods. The Commercial Intelligence Journal, a weekly publication of the department of trade and commerce at Ottawa, secures from time to time, enquiries for Canadian products, and for convenience of classification gives each of these enquiries a key number. We have compiled several which will interest our readers, and when following these up, write direct to Ottawa, mentioning the key number, thus avoiding delay.

4661. **Machinery and tools.**—A firm of machinery merchants in Malö is desirous of importing all machinery for iron, steel and woodworking purposes; also pipes, pumps, sanitary goods, elevating goods, transportation goods, railway materials, rolling stock, small tools of all kinds, belting, fixtures, oil, greases, hardware, casters and machine tools.

4669. **Machinery, tools and supplies.**—A large firm in Copenhagen are interested in importing all kinds of machinery, tools and supplies, for metal work, iron foundries, and machine shops, as well as woodworking plants; also tinsmiths' tools, belting transmission and sharpening wheels, and all similar products, in which they have an old and established connection.

4671. **Machinery.**—A Norwegian concern wants to have the sole selling rights for Norway for a Canadian firm in a position to export all kinds of woodworking and metal working machinery.

4662. **Machine Tools.**—A firm of machinery merchants in Copenhagen are open to import machine tools of all kinds.

4663. **Hand Tools.**— A Copenhagen firm desire quotations for hand tools for mechanics: pincers, pliers, hammers, taps, dies and drills.

4664. **Pumps.**—Canadian manufacturers of pumps, especially centrifugal and triplex pumps, should send catalogues and prices to a Copenhagen house.

4665. **Machinery supplies and machines**—A Stockholm firm are interested in sole agencies for Sweden for machinery supplies and machines.

4666. **Woodworking machine tools.**—A firm in Sweden are desirous of representing a Canadian firm in a position to export woodworking machine tools; also mechanical steel working tools.

4668. **Belting, leather, rubber, cotton, etc.,** are demanded by a firm in Stockholm.

4620. **Agricultural implements.**— A firm in Goteburg would like to hear from a Canadian exporter of hay forks, 2 and 3 prong, manure forks, 4, 5 and 6 prong, and spreading forks with 4 prongs; also shovels and rakes (iron), with 12, 14 and 16 prongs, and wooden grass rakes with 24 prongs.

4627. **Agricultural implements.**—A firm of hardware merchants in Copenhagen would be glad to have catalogues and prices from Canadian exporters of agricultural implements.

4628. **Agricultural implements.**— A Swedish importer desires to import hay forks, 2, 3, and 4 prongs, mangle forks, 4 and 5 prongs, manure forks, 4 and 5 prongs, rakes (iron), 10, 12, 14, 16 prongs, and wooden rakes, 10 prongs and larger.

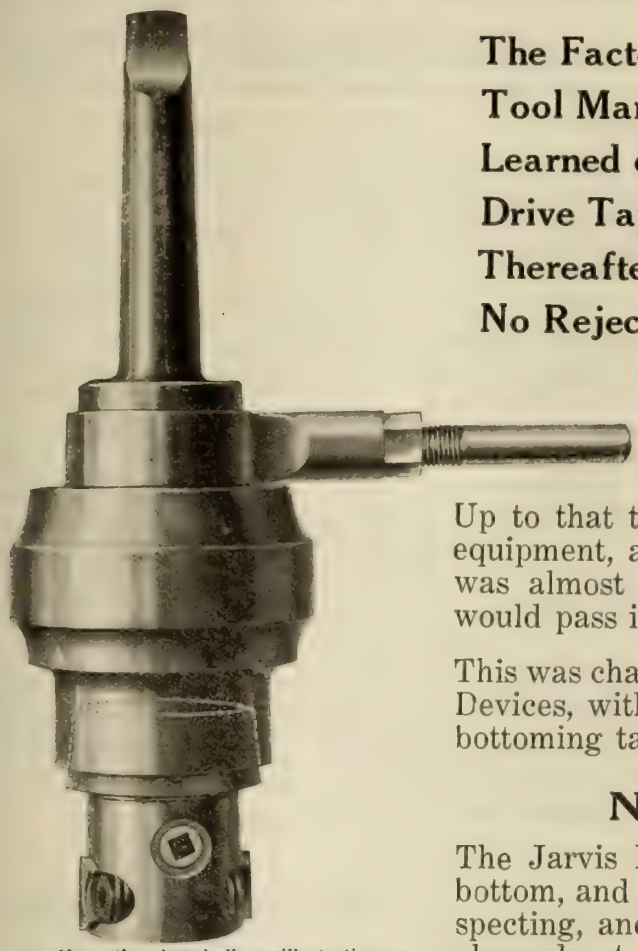
4672. **Tools, etc.**—A Christiania concern desires to import all kinds of tools, as electric and pneumatic tools, etc.; also belting, steam pumps, fans, transmission ropes, packings, etc.

4673. **Tools.**—Canadian manufacturers of files, hammers, pliers, etc., should send catalogues and price-lists to a firm in Copenhagen.

4670. **Mechanics' tools and machinery.**—A Norwegian concern would like to import mechanics' tools and machinery, also rails up to 12 kilogrammes per metre.

4654. **Leather belts.**— Established manufacturers' representative in Jamaica wishes to receive offers from Canadian manufacturers of leather belts. He reports a fair demand for the above-mentioned commodity, and if prices are right, he can supplant considerable United States supplies.

4655. **Tubular wheelbarrows.**—A Johannesburg firm of hardware manufacturers' agents are looking out for a manufacturer of tubular wheelbarrows, with a view of representation in South America on a commission basis. All business transacted to go through a shipping house of repute.



4656. **Wrapping paper and paper bags.**—A Cape Town firm, with branches in all centres of the Union and Rhodesia, make enquiry for the representation of Canadian wrapping paper and paper bags.

4658. **Zinc spelter.**— A Japanese firm in Yokohama, is anxious to receive quotations on zinc spelter, 98 and 99 per cent. This firm advise that they can use about 100 tons per month, and wish to import direct from Canadian producers.

4659. **Open hearth steel ingots.**—A responsible foreign firm of long standing is in the market for 24,000 tons of open hearth steel ingots. Delivery 2,000 per month. Quotations desired immediately.

No degree of care can eliminate every possibility of danger from grinding wheels revolving at a high speed. If there is an unknown defect there may be some interruption say a sudden jamming—that may result in a bursting of the wheel. Against an accident of that kind the wheel should have guards. These are usually in the form of protection hoods strong enough to arrest the broken fragments. Only sufficient surface of the wheel should be left to permit of operations. The remainder should be carefully hooded. An expanding or contracting rim provides a useful method of regulating the aperture. Of course, the hood should be of robust construction, with a secure connection to the floor. It may have to be removed for some jobs, in which cases flanges of some kind are indispensable.

WORKED LIKE MAGIC

Note the dotted lines illustrating position and size of Friction Cone.

The Factory Manager of a Large Tool Manufacturing Concern Learned of the Jarvis Friction Drive Tapping Device, and Thereafter There Were No Rejections.

Up to that time they had been using regular standard equipment, and the bottoming taps did not bottom. It was almost impossible to tap the holes so that they would pass inspection.

This was changed like magic when the 20 Jarvis Tapping Devices, with Cone Friction Drive, took the place of 90 bottoming taps.

No Inspection Needed

The Jarvis Friction Tapping Device taps the holes to bottom, and then runs in a second time to do its own inspecting, and when it finishes, every hole is thoroughly cleaned out to bottom.

Very little pressure is needed to drive the device.

The Drive is controlled by pressure on the machine spindle.

Stripped threads are unknown.

Holes tapped in toughest metal with little tap breakage.

Standard Chuck.

No special taps required.

The Taps freely started and stopped while rotating.

Adaptable to Drilling Machine or Speed Lathe.

Ask us about the Jarvis High Speed Tapping Devices, which act without clinching or binding.

And the Jarvis Quick Change Chucks and Collets, for Drilling, Counterboring, Tapping and Stud Setting.

We are sole distributors.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

What Are You Waiting For?

A study of charts, reports and general statistical data clearly shows that business is coming back—slowly it is true, but very certainly.

Many manufacturers, financial men and others have long since accepted the inevitable, realizing that business, having hit the bottom, is not going to immediately rebound to pre-depression levels. Business rolled downhill with considerable speed and force, but it gathered no momentum for the uphill journey. It will require a steady pull and lots of power to climb out of the valley and up the slope to the next peak.

There's going to be no quick-cure for present industrial ills. Good exercise and a good diet is required. The arteries of your business may have commenced to harden, blood pressure may be high and your reserve force low. The healthy exercise of hustling for orders will do a lot to restore health and advertising will supply the vital vitamines.

There's no use waiting like Micawber for something to turn up. We are living to-day just about where we left off in 1914 to go to war. The four or five years of easy-come, easy-go have got to be forgotten. They were abnormal, freak years — by-products of the world's greatest upheaval. Forget their sales records—their profits.

When business comes back it's going to be chummy with the man who goes out to meet it. If you need equipment to enable you to manufacture more efficiently—buy it. If you have something to sell—go out and sell it. Get back of your salesmen and convince them that the time for waiting is past. Give them, particularly, the encouragement and inspiration that good advertising always gives.

KAELIN ELECTRIC STEAM GENERATORS

Their Field

Any mill or factory developing its own power which has surplus electric energy during the whole or any considerable part of the day.

Any mill or factory operating on bought power purchased on a "flat rate" basis, but which is not using all the power allotted to it.

Capacities

These Electric Steam Generators are built in sizes from 600 to 25,000 K.W., corresponding approximately to 60 to 2,500 Boiler horsepower.

They can be operated by alternating current only, and are built for voltages varying from 550 to 12,000.

Advantages

Their first cost including installation is low compared with any type of coal or oil-fired boiler plant.

They are safe, clean, easily regulated, require but little attendance and take up very small floor space.

They can be operated in parallel with existing boilers or can be installed close to their work.

Information and prices promptly submitted on receipt of particulars as to your conditions.

The Reason for .000,005" Accuracy

Every gage you use, whether it's a master, inspection or a working gage, is based on some standard of measurement. If this basis of measurement is a set of gage blocks, built-up to form various dimensions, the nearer those blocks individually are to absolute accuracy, the smaller the errors in the built-up stacks.

That's why Hoke gages are made and **guaranteed** accurate to within five-millionths of an inch. They give you a basis to work from that practically eliminates error at the start and ensures closest possible accuracy in your gages and in all the measuring you do with them.

Even though shop tolerances are usually to thousandths, gages set to Hoke block "millionth of an inch" accuracy are bound to be more accurate — and keep your work more accurate — than when set to other standards.

And remember this, Hoke Gages cost no more than other high-class gage blocks of less guaranteed accuracy. They are so reasonable in price that any shop can well afford a set. They're sold singly, too, or in sets of 5, 10, 34 and 81 blocks

The Hoke Gage Catalogue should be in your reference library—it's yours for the asking.

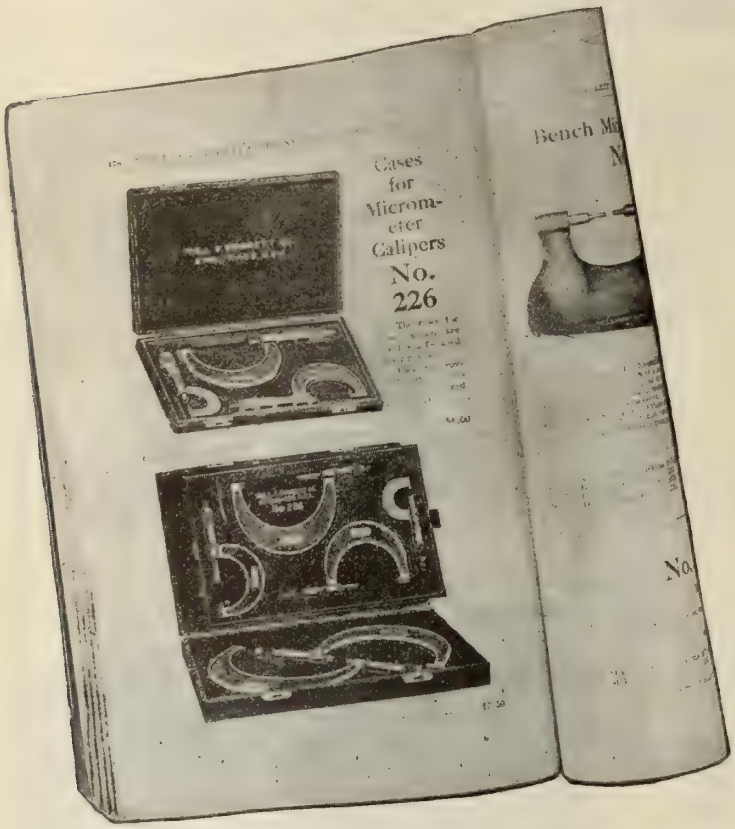
PRECISION GAGES



Laboratory Accuracy at a Toolroom Price

The 81-block set shown here will handle measurements between .200 in. to over 10 inches by increments of .0001 in.

Sets of 103, 85, 34 and 5 blocks are also sold and single blocks or any combination of standard blocks can be bought, if desired.

Have You Seen These Tools?

MICROMETER CALIPER SET
No. 226 L

Four Starrett Micrometer Calipers reading to ten-thousandths—sizes 1-inch, 2-inch, 3-inch and 4-inch. The sizes included afford sufficient capacity to cover a very wide range of work. Each of the four micrometers in the set is equipped with the Starrett lock nut and ratchet stop. Details of this and other sets of Starrett Micrometer Calipers are given on pages 172 and 173 of the new Starrett Catalog No. 22 "3" If you have no copy of this catalog at hand, we will gladly send you one free. Write for it.

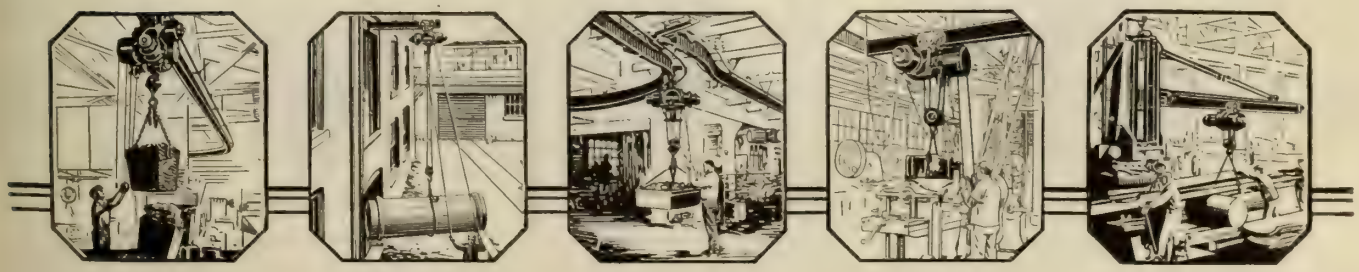
THE SHEPARD ELECTRIC LIFTABOUT

For Precision of Control

A CHANGE in elevation of only a few inches; slight shift to right or left. All accurate and exacting work is possible with a *LIFTABOUT*, for it is always instantly responsive to its operator. In the foundry this new and smaller electric hoist with foundry control is adaptable to every lifting and conveying job—the precise work of pouring crucibles, handling patterns, flasks, casting, and lowering copes, as well as general rehandling in and around the plant.



A *LIFTABOUT* and one man, its operator, provide a perfect combination of speed and precision, which performs necessary handling work in less time and with far more efficiency than is possible by manual methods. All parts, both mechanical and electrical, are protected from dirt, dampness and fumes by tight metal housings.

Now is the time to scrutinize your load moving costs, to "weed out" inefficiency and to slash overhead costs. The *LIFTABOUT* method for lifting, carrying and putting down loads could not be offered at a more opportune time. It effects savings in time, labor and money that make it a paying investment from the very first day of installation. Due to quantity production and standardized manufacture, it is surprisingly low in cost.

Investigate *LIFTABOUT* economies for your plant. Shepard Engineers will gladly acquaint you with its many advantages.

Shepard also builds electric cranes and hoists in capacities to 30 tons.

Shepard Electric Crane & Hoist Co.

Increase the Consumer's Interest

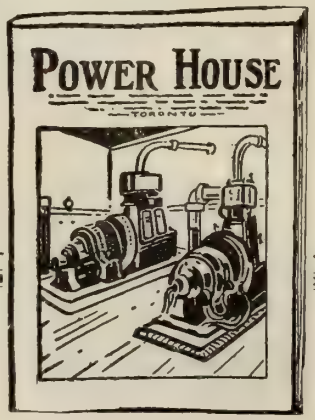
Create a Livelier Demand for Machine Shop, Power House and Foundry Equipment

ARE you manufacturing equipment for Machine Shops, Metal Working Plants, Power Plants and Foundries? Does the consumer know your products? Does he know their quality sufficiently to insist upon getting them when he places an order with his hardware dealer? Carefully weigh these questions. Then consider the advisability of reaching the consumer through the columns of MacLean Technical Newspapers. You can probably use one of the following group.

CANADIAN MACHINERY AND MANUFACTURING NEWS—issued weekly, serving the Canadian Machinery, iron, steel and general metal-working industries: it is read by the men who buy equipment, proprietors, purchasing agents and other executives: its editorial contents are authoritative and comprehensive.

POWER HOUSE—published twice a month, serving steam, electrical, water and gas power plants, in addition to refrigeration plants, in all parts of Canada. It, too, reaches the men who buy equipment; it, too, is the leading authority of the Dominion in things pertaining to its field.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly, rendering indispensable service to the grey iron, steel and non-ferrous foundries of the country. Proprietors, executives and foremen read it diligently.



You can awaken new interest in your products by advertising them to the consumer through MacLean Technical Newspapers. Write for complete information.

GTD

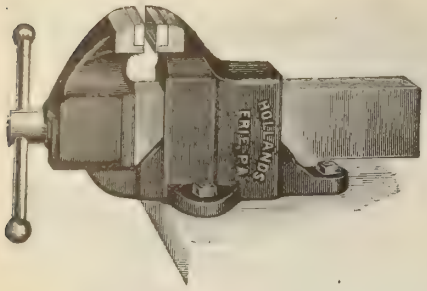
Complete Small Tool Equipment for Every Industry

GTD QUALITY—

the Kind that Endures and Performs

The quality of tooling equipment and measuring devices often has a more important bearing on output than the machines on which they are used. In this connection the accuracy, convenience and stamina of GTD small tools for machining and measuring show to advantage.

The "Acorn" Die, the "Gun" Tap (the original spiral pointed tap) GTD *High Speed* Screw Slotting Cutters, GTD Limit Snap Gages, the GTD Special Oil Drill and the GTD Adjustable Reamer are a few special tools known wherever high production requires the best tooling equipment.



The quality and remarkable performance of these special tools, we believe to be a very fair index of the excellence of our *standard* threading tools, drills, reamers, etc., stocks of which are available all over the country.

We can give you *concrete samples* of GTD tool performance on production jobs in metals varying from soft brass, through cast iron to monel metal and vanadium steel, all of which will show you that GTD can furnish the proper tool to give the maximum results on *your particular job.*

May we send you our new No. 46A catalog? Your copy is ready *now.*

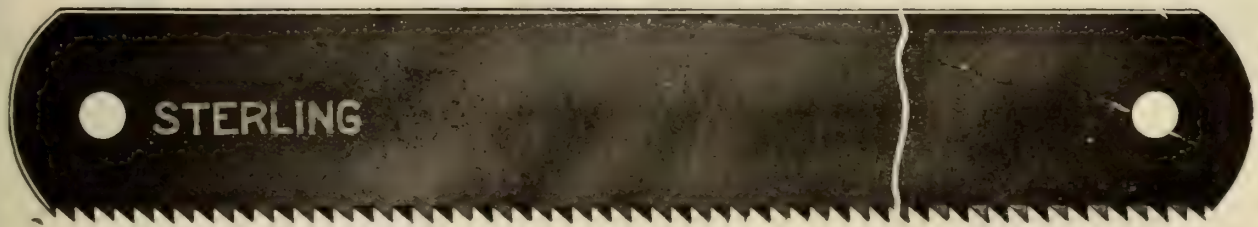
Hand Protection

Means Better Work

Mitten Style No. 681



Steel-Grip WORK MITTENS

and work gloves give complete hand **protection** plus hand **comfort.** The same reinforcement (small steel ribbons over strips of tough leather) that protects the hand also gives so much extra wear that these mittens and gloves last almost indefinitely. Sewed closed with steel thread, they are absolutely rip-proof. The steel reinforcement does not interfere with flexibility. Your workmen equipped with Steel-Grips will dig in with a will.

Write us to-day for suggestions on your hand protection problems. We can save you money on your work glove purchases.

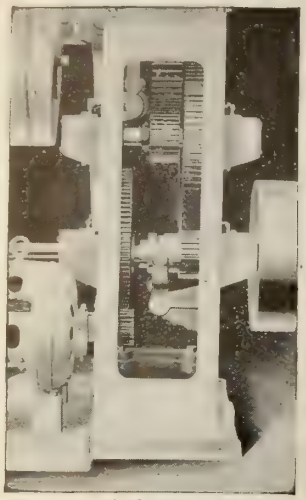
HACK "STERLING" SAWS

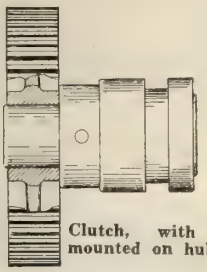


MANUFACTURED BY
DIAMOND SAW & STAMPING WORKS -:- BUFFALO, N.Y., U.S.A.

THE JOHNSON FRICTION CLUTCH

IS USED ON THE

PEERLESS DOUGH MIXER



Courtesy of the Peerless Bread Machine Co., Sydney, O.

A No. 4 single clutch is used to facilitate starting and stopping.

Lubrication is a necessity for all running bearings and frictions and an occasional application is all that is necessary.

Adjustment of the Johnson friction clutch is simple. A small screw moves two taper blocks in toggle levers, giving greater expansion to ring — thus more gripping power.

The Johnson friction clutch is a small, compact and very powerful device for machinery of all kinds where medium or light power is transmitted.

Clutch, with gear mounted on hub.

GOODELL-PRATT

1500 GOOD TOOLS

We Welcome Any Kind of Tests for Accuracy

You may be prejudiced about machinists' tools, but standards are not. If you give our precision tools the most exacting tests for accuracy in comparison with other makes, the results will be more convincing than any words of ours.

Micrometers, Rules, Squares and Gauges can all be tested for accuracy before you buy them, but Calipers can only be judged by general appearance.

Look at Goodell-Pratt Calipers, each one has well-proportioned legs of tempered steel—we don't make soft ones. The points are well shaped and come together accurately. The springs are strong and screws are smooth and even. Quick nuts work freely and do not bind.

If you are proud to own good tools write for "Tools for the Toolmaker"

BROWN-BOGGS

B B

Make Sure of the "B-B" Trade Mark

It is a Guarantee of Reliability

The "B-B" trade mark on power presses, shears, tinsmiths' tools and canners' evaporators, and sheet metal working tools of every description, is an iron-clad guarantee that it will give satisfaction on the work for which it is built. And because every tool before it leaves the factory is rigidly tested, we **know** that its merit is beyond question.

We shall be glad to send you catalogs fully describing those machines in which you are interested.

300 H. P. double reduction drive on mine hoist. Link-Belt silent chain as first reduction and a quadruple-width Link-Belt Roller Chain as second reduction.

LARGE RATIO SPEED REDUCTIONS

WITH a single Link-Belt Silent Chain Drive we have made as great a reduction as 20 to 1. In other words the speed of the driven shaft has been reduced to 1/20 of that of the driver shaft, through a single drive.

Where conditions permit, it costs less to handle the total speed reduction through one unit. In this way, the countershaft is eliminated, with its bearings, extra wheels, etc.

For drives transmitting large horsepowers, and thus requiring relatively large diameters for the smallest wheels, and especially in limited spaces, a double reduction drive, using Link-Belt Silent Chain for the first reduction and Link-Belt Roller Chain for the second reduction, has many advantages. It is compact, efficient, economical, and flexible; yet positive.

Conditions vary, and one rule cannot be applied with the same success to every case. That is why we ask you to take your problem up with our experienced drive chain engineers. They will help you determine the best drive for the purpose. Address nearest office.

D.K. McLAREN'S

GENUINE BRITISH OAK TANNED

LEATHER BELTING

GENUINE OAK

What Are You Paying For Wasted Power?

Transmission costs are high enough these days without taking unnecessary chances that are liable to add to them, at the same time lessen production.

There are good reasons behind our claim that D. K. McLaren's Belting reduces your transmission costs. In the first place only the toughest parts of hides, selected by experts, are used. These **backs** are subjected to the genuine British Oak Tanning, a process that not only adds to their toughness but imparts a wonderful flexibility to the leather. It is this combination of toughness and pliability that gives to D. K. McLaren's Belting that gripping quality which prevents slippage and other troubles.

Is your belting efficient under all conditions?

THE Main Belting Company has perfected a method of making either Leviathan or Anaconda endless in a factory. The belts produced by this method are positively unequalled. They are scientifically proportioned to the size and character of the load to be handled. They are cured under tension, as is every foot of belting we make, and the result is a belt of exactly the right length, in which stretch is at a positive minimum, with flexibility and driving power at the maximum. These belts can be installed with absolute confidence.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.

It is designed to cut one gear at a time and at a speed which eclipses all other methods.

All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for 10 machines

It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.

See illustrated article in all technical magazines.

Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

Maximum Power Transmission Do You Want It?

Then Try Out

"P.M.S" BELTING

This remarkable belting gives maximum transmission because it has been especially designed to do so. It has turned the belting world upside down because it has successfully accomplished the solution of an age-old problem. This problem of efficiently transmitting power that is very costly to develop comes very close home to every engineering man in every industry. "P.M.S" very likely solves the problem of some difficult drive of yours. We ask you in your own interest to examine some "P.M.S" Belting. Observe that it excels in freedom from slipping, stretching, breaking and time lost for repairs and adjustments. It has marvellous strength and stands up to heat or cold and wet or dry conditions. It is made from toughest Sea Island Cotton rubberized to prevent slipping and protect from moisture.

What About YOUR Needs for Belting?

"P.M.S" Is Manufactured Exclusively by

His Safeguard— a PHOTOSTAT Print

Even your most conscientious machinist doesn't have to "make sure" about any figures or lines on a PHOTOSTAT print. He knows that the print was made directly from the original drawing, not from a tracing, and

> The PHOTOSTAT makes no mistake. It makes photographic facsimiles.

There is always the possibility of errors in blue prints made from tracings. PHOTOSTAT prints are absolutely accurate.

It takes hours and in some cases even days to make tracings and blue prints. PHOTOSTAT prints are produced in a few minutes.

Tracing takes a skilled draftsman. The operation of a PHOTOSTAT requires only a boy or girl.

Tracings and blue prints cost dollars. PHOTOSTAT prints cost cents.

The ACME

3/4 Inch Six-Spindle Semi-Automatic NUT TAPPER

THE design of this machine will readily be appreciated by observant engineers and mechanics. It is of substantial dimensions and is exceptionally strong where strength is needed to withstand the most arduous service—yet it is quick and easy in operation.

Each spindle is equipped with Automatic Lifting Service, which lifts the spindle to allow the automatic feed to place the nut under the tap.

Spindles have counterweights to facilitate handling and to prevent breakage of taps by spindle starting the taps in the nuts too suddenly. All gears and pinions are cut and made of good quality steel.

These are but a few of the features of this machine. Our catalog, which we will send upon request, contains a complete description.

TRUE BEARING SURFACES GROUND WITH NORTON ALUNDUM GRINDING WHEELS

Tedious, slow and costly "scraping" has been successfully replaced by a grinding fixture and a Norton Alundum grinding wheel.

To insure the necessary accuracy, the grinding wheel must be of an abrasive, grain, and grade to "cut true" without loading or glazing, and without heating.

A Norton Alundum grinding wheel, grain 46, grade J, in the illustration was proven to possess all these necessary qualities. The saving was decidedly worth while.

We would be pleased to advise further details and to consider your particular problem individually.

Punch Presses and What They Can Accomplish

Getting the Most Out of the Machine by Observing Certain Principles and Adopting Time Saving Devices—Hub Punching Die —Blanking and Embossing Die—Special Extension Gauge

By J. H. MOORE

THE versatility of the punch press is unquestioned. It is used in practically every industry, and the variety of parts blanked, punched, drawn and formed on such machines is almost without number. Like any other machine tool its productive capacity largely depends upon the care taken from the date of installation, so that when one speaks of what punch presses can accomplish, they must take into consideration many factors.

For example, the foundation. Unfortunately some shop foremen do not consider this an important point, and place the machines on poor flooring with the result that constant operation makes everything loose, and excessive vibration takes place. For ordinary sized presses, a good stout flooring is sufficient for the purpose but make sure that the base is well secured to the floor. When installing heavier presses, a cement foundation should be provided, the size depending upon the weight and capacity of machine.

The Question of Belts

The belt on a press seems a small item yet it is a very important point, because it can easily spoil the machine's production. Every time the belt slips off the flywheel it means a loss of time, so that when installing any press, the possibility of this danger should be watched carefully. The solution to the trouble is perfect alignment. Make sure the flywheel of press lines up with pulley on shaft, and watch carefully the lacing of belt, so that it runs smoothly. Should readers imagine all this care unnecessary read the following true story. In a certain plant not far from Toronto, a complete line of presses were all addicted to the same habit, viz, throwing off their belts. Unfortunately, they would always throw off to the inside, the belt would get mixed up in the clutch, the result being it would come out considerably chewed up. The loss in time was enormous. Finally, a careful inspection was made of the alignment, adjustments took place, and since then, production at this particular plant has increased wonderfully. The same presses are now completing parts steadily, the operators are better satisfied, and naturally the management are pleased, all through a small belt problem having been successfully solved.

Setting the Ram

Although the press operator should know better, it is a recognized fact that considerable wasted time is consumed during setting up. Allowance should be made for the thickness of stock to be punched or drawn and lest this should

Drawings obtained through the courtesy of Brown, Boggs Co. of Hamilton.

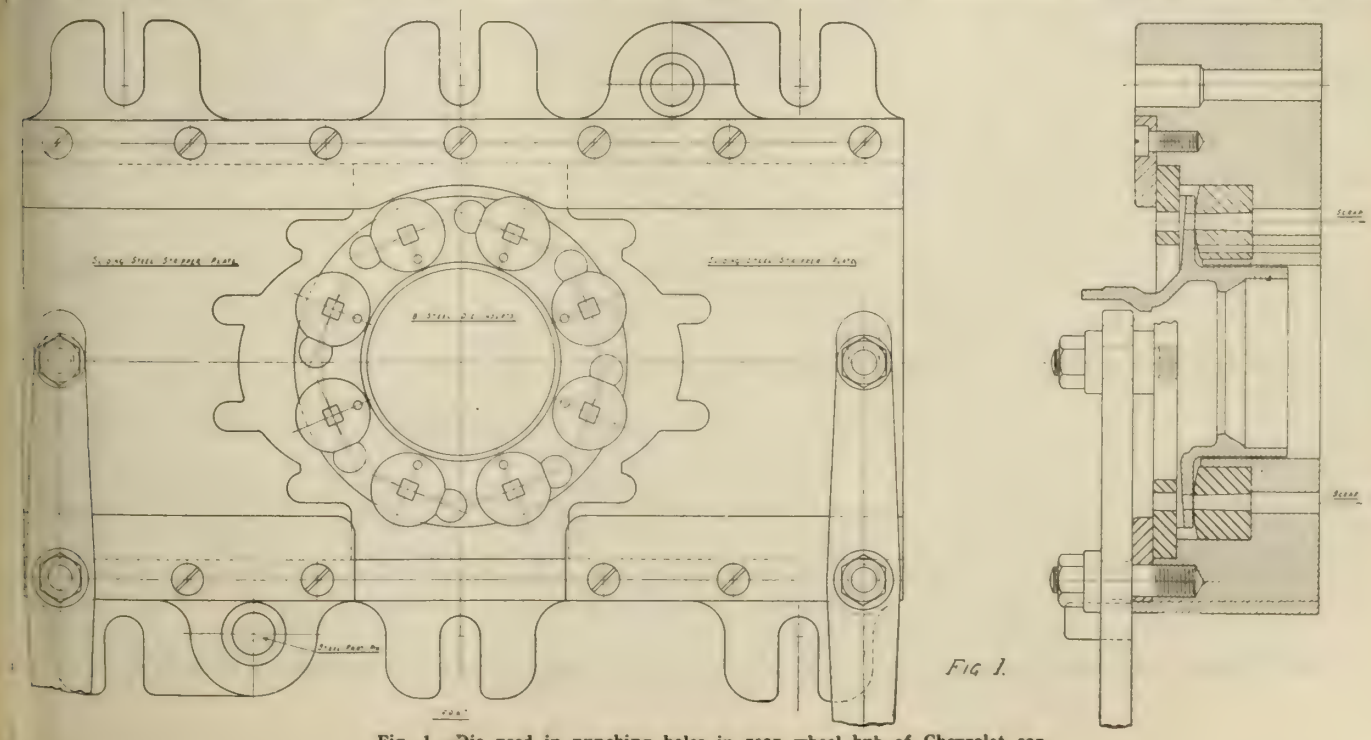

Fig. 1.—Die used in punching holes in rear wheel hub of Chevrolet car.

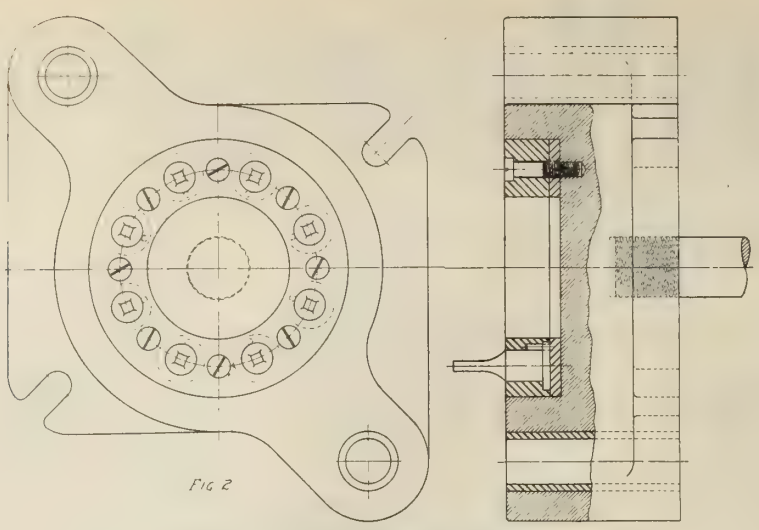

Fig. 2.—Showing method of holding punches in position.

seem an unnecessary warning, we will tell another true story.

Not long ago, a set up man, who had been on the job for several years, started to line up a pair of dies. He turned over the ram by hand until he had everything correct, or at least, to his mind correct, then tightening both upper and lower bolster in position he decided to try out the dies by power. "Are you sure you made allowance for the stock, Bill?" asked another workman. "What do you think I am? Sure, I allowed for the stock," and with that he inserted a strip of material, pressed the treadle, after which things happened very quickly.

First, he discovered he had NOT allowed for the stock and the press jammed. The jerk on the belt, pulled the machine clean off its foundation and carried it up to the shafting. Luckily, some one shut off the power, and the belt managed to support the press, otherwise it might have dropped through the floor to the next storey, for this incident occurred on the top flat of a large manufacturing establishment. The story proves that you cannot be too sure, and that hand power is quite sufficient until you are absolutely certain everything is O. K.

Design of Dies

The production secured from a press largely depends upon the equipment used. A poor set of dies on a good press will not help production. Whenever possible, use guide pins, and have them well lubricated, for these ensure proper alignment of upper and lower die and punch. Consider the question of replacement and make the steel parts in sections if at all possible, backing these up with a heavy cast iron wall. A solid chunk of tool steel does not necessarily mean a good die and by carefully planning the design you reduce not only the first cost, but subsequent renewal of parts.

Where sheet metal parts are produced on a press and when a high rate of production is very essential, you can often increase the output of machines by the use of automatic feeds. Not only does the placing of such feeds increase production, but it makes it safer for the operator, as he never needs to put his hand near the dies. He can also attend to more than one press. Usually, the simple or double roll, grip gravity or dial feeds are employed; the first two being automatic, the next mentioned partially automatic.

When a single or double roll feed is fitted to the press, the stock is usually carried on a spool in strip form. The operator merely enters the strip between the rollers and the press accomplishes the rest. Every time the ram ascends, either a rachet or rack operated feed is automatically operated through a connecting rod between the end of the crank shaft and feeding mechanism. We are not interested, however, in the various methods of applying such feeds as we are in the value of them, viz, aids to production.

The same fact holds good on gravity feeds, for the operator has no time to waste. The press is operating continuously and it is up to him to keep the hopper, or inclined slide, filled with blanks. The push, dial and rotating feeds are also splendid, for again the operator must be right on the job, filling the dial completely. Dial fed presses are widely used by makers of hardware stampings and for any industry using articles having several forming operations. The use of the feed mechanism permits a series of dies to perform the different operations on the one press.

Because you have a press, or number of presses in your plant, which have been turning out a certain volume of work for several years, is no reason why the same machines cannot produce still more. What a press will accomplish depends to a great extent on how well the owner makes use of it. We have so far discussed the foundation, belt troubles, setting of ram, designs of dies and possible types of feeds to use, but how about guards?

Value of Guards

A plant superintendent, who is prejudiced against guards, said to us recently "Guards—they are a nuisance and only hold back production." Our answer was brief and to the point. "If they are unnecessary why should one firm alone spend more than $10,000, feel satisfied and after the workers' first grumbling had ceased, increase their production over 10 per cent." We proved this point to him, with the result that he may become a convert. Without question, properly designed guards will increase production. At first, you may have difficulty with the men who are

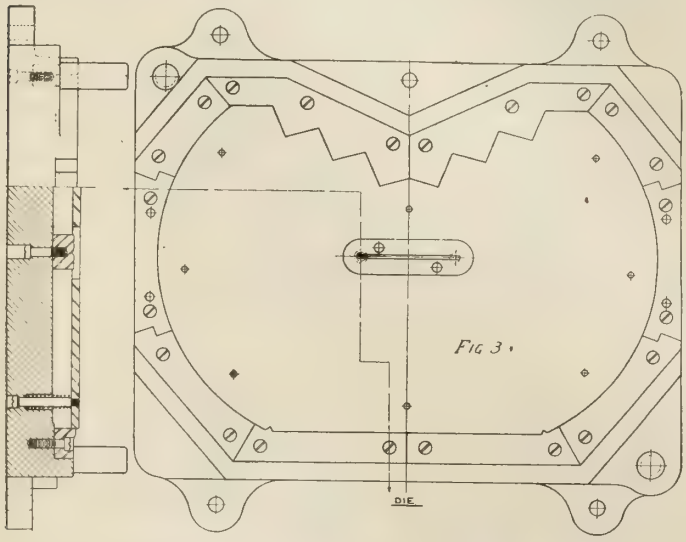

Fig. 3.—Blanking and embossing die for washing machine part.

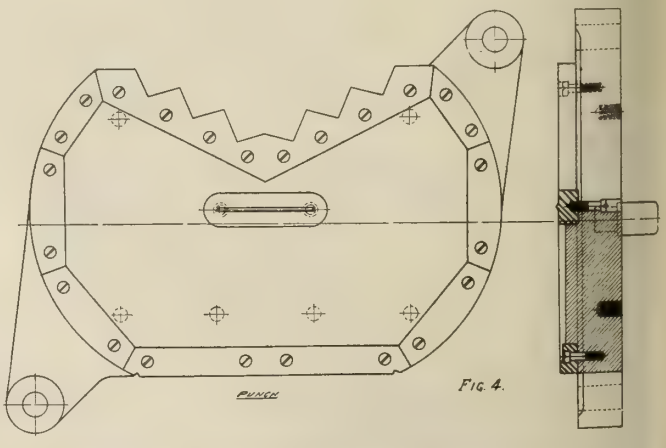

Fig. 4.—Blanking and embossing punch for die shown in Fig. 3.

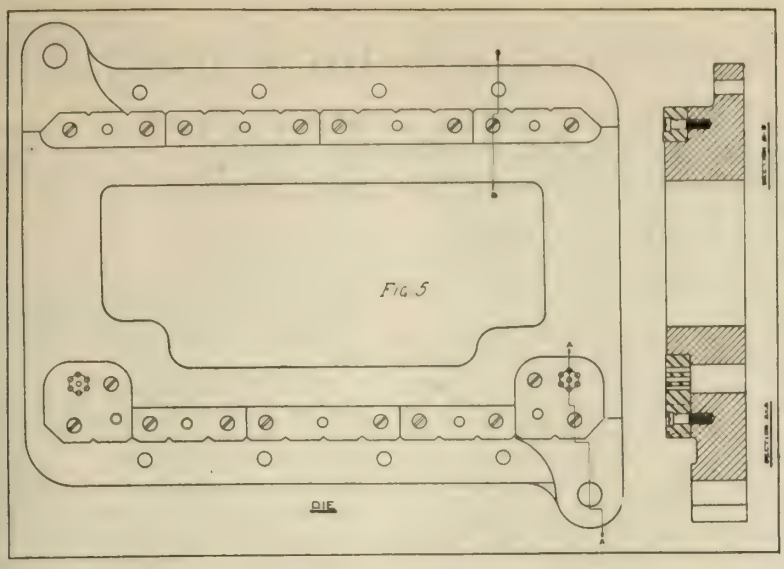

Fig. 5.—Construction of notching and perforating die for washing machine parts.

not in favor with the safety move, but if you persist in their use, the final results will be gratifying. Make the guards as simple as possible. Once you get into any intricate design you will find something going wrong with them continually you will become disgusted and discard them. Do not condemn the use of guards because of some unfortunate experience, but rather design a simple type, using it to help the press accomplish the best that is in it.

Leaving these points for the reader to think over at his leisure, we will illustrate several dies which have helped to increase production, and have also reduced manufacturing expense. For example Fig. 1.

Here we see a die designed to punch the rear hub of wheel for Chevrolet car. Eight 25/64 in. square holes are punched at one time, and as will be noted from the sectional view, special stripping arrangements had to be provided for, owing to shape of piece.

The hub is placed in position, and the stripper, which is in two pieces, is slid over until it covers the part. The arrangement of the stripper is simple, yet very effective, for the operator merely grasps both handles and pushes outward. It will be noticed that two steel pilot pins are used to align up the top and lower members of die.

Fig. 2 shows the upper holder, and the method of holding punches in position is worth noting. Each punch is flanged and fits into a steel ring. The flanged head hits up against another steel ring and both rings are fastened to the cast iron holder by means of eight filister head screws as shown. In addition to this, each punch is pinned in position to prevent any chance of turning. The square style of punch makes this precaution necessary.

Washing Machine Dies

The next illustration Fig. 3 shows the lower half of a blanking and embossing die used in one operation on a washing machine part. This die is an excellent example of the use of small sections of steel in die design. Note how fully they are tongued in some cases to ensure proper fastening and location. The sectional view illustrates method of holding. This also shows the spring stripper used, and the two steel guide pins. Note the small embossing die in center. Fig. 4 illustrates the design of punch, and as this is self-explanatory we will pass on to Fig. 5 which shows a notching and perforating die, also used in washing machine parts. This die handles two sides, and again we notice the value of small steel sections in making up a die of this nature. The sectional view depicts the details clearly, and in plain view it will be seen how corners of die blocks are arranged. There is no need to show the punch block, as Fig. 6 illustrates the assembled die. The guide blocks in this case are fastened to the lower bolster, and the spring stripper is attached to the upper punch block.

The remaining illustration, Fig. 7, depicts a special adjustable hold down extension gauge used in conjunction with brake band dies. In this case, the stock

Getting the Best Results Out of Your Export Trade

Manufacturer and Export Merchant Should Co-operate—Intensive Selling Campaign Can Be Carried On Through Exporter—Prices and Complete Information Should Be Given Promptly

By GLOWACKI R. PARKER

IN approaching this somewhat broad subject I am fully aware of the danger of generalization, which too often does not cover the specific point or problem, while similarly the risk of contradiction is great in attempting to pyramid a generalization upon the isolated instance. My intention is to try to outline the real functions of the merchant house in foreign trade and to show that the interests of the manufacturer and exporter are mutual.

I may add this is not a plea for the abandonment of direct selling, which admittedly has its merits under certain conditions, nor yet a general condemnation of past practice in the relations of manufacturer and exporter.

The war period created conditions quite without precedent in the annals of American foreign trade, and it is not surprising that there grew into being almost over night an extraordinarily large crop of foreign traders whose overseas experience was largely limited to a trip to Coney Island by ferry boat, and whose decline was destined to be as rapid as their rise. That certain disastrous experiments in foreign trade would result might readily have been predicted.

To properly treat the subject of the relationship between manufacturer and exporter, it is first necessary to briefly examine the function of the latter, and to establish the fact that he is a useful economic link in the chain between American producer and foreign consumer.

The author is a member of Frazar and Company and this paper was presented at a recent group session of the Ninth National Foreign Trade Convention, held in Philadelphia.

There is perhaps in some quarters an undercurrent of feeling that success in the foreign field can only be achieved by direct dealing with buyers. It is argued that this permits of:

1—A more intensive selling campaign
2—Direct control of markets
3—Control of selling organization
4—Building up of good will in the manufacturer's own name
5—The elimination of the exporter's profit, and consequent reduction of cost.

Now without denying the force of these arguments, and their undoubted application to specific cases, the answer to most of them can be found in the subject of this paper, i. e., closer co-operation between manufacturer and exporter. The latter is quite justified in replying somewhat as follows:

Points to Watch

1—An intensive selling campaign can be carried on quite as effectively if the manufacturer will only regard the exporter as a part of his own selling organization, and will support him, and supply him with needed information to the same extent as he would his own salesmen.

2—The manufacturer can control the foreign market to at least the same extent as he can the domestic market. He can and should examine the costs laid down in foreign port, and in consultation with the exporter establish the foreign selling price, raise or lower it to meet competitive conditions, in the same manner as an eastern manufacturer would regulate prices in San Francisco.

3—The advantage of direct control of the selling organization is at best theoretical. Neither branches nor permanent salesmen of the parent company can report to head-quarters in person with any degree of frequency, nor can their movements and operations be closely watched. The merchant house on the other hand, whose profits are derived solely from successful selling, must see to it that unprofitable sales do not occur, and that traveling and other expenses are incurred where they will do the most good.

4—So far as the good will attaching to the specific product is concerned, it is to the interest of the exporter to foster a particular brand or trade mark, and encourage its sale under its own name.

5—The theory of saving in cost by eliminating the exporter's profit or commission does not bear the light of investigation. Let us suppose the manufacturer decides to open his own foreign office in a given country. A branch office of the most modest pretensions costs in the neighborhood of $2,000 a month. A first-class manager's salary will be about half that, while a minimum of two or three assistants, rent, cable bills and travelling will absorb the balance. This would hardly provide for very much local advertising, entertainment, or miscellaneous expense. How-

General view of Montreal port, Canada's chief water terminus.

ever, using this figure, we have an annual cost of $24,000 per year.

Assume now that the exporter charges 10 per cent. (he seldom gets that much), and that this same percentage can be alloted as branch office expense. It is evident then that $240,000 of business must be done to break even. At 5 per cent. this figure must be doubled. Furthermore, the office must be maintained in and out of season. I submit that the average manufacturer who can count on that much business from the territory which can be served by one foreign office and maintain it year after year, is over optimistic. The merchant can afford it because of the diversity of his sales.

Exporter's Arguments

In addition to the foregoing, the exporter can advance a few arguments of his own, which may be summarized as follows:

a. The exporter takes the merchandise off the manufacturer's hands at the latter's factory, and pays for it on at least as favorable terms as domestic buyers.

b. He takes the credit risk and if the foreign buyer fails to pay, the manufacturer gets his money just the same, and need, therefore, concern himself with only the exporter's credit.

c. Of necessity, considerable capital is required to finance an export shipment, which, if it were not supplied by the exporter, would have to be furnished by the manufacturer, and, in consequence, so far as foreign business is concerned, the working capital and credit of the manufacturer are increased by those of the exporter.

d. The exporter, through his branches or affiliations abroad, lives with his clients. In most cases an intimate association of years' growth has been built up. Buyer and seller meet socially, they belong to the same clubs, Chamber of Commerce, or other civic bodies, they have many common interests quite apart from the purchase of goods. Traveling salesmen can never build up such a relationship, and even a permanent branch must take years to develop it.

e. Perhaps the most important point of all is that the exporter is often an importer as well. He is then in a position to foster reciprocal trade, thereby building up good will toward this country, to say nothing of increasing the purchasing power of buyers. The incidental contribution to stabilization of exchange, and the creation of credit balances constitute an asset which cannot be overestimated.

The exporter might readily go much further in his exposition of the service he performs, but the foregoing is sufficient to indicate in a general way that he occupies a useful position. Admitting this to be the case, it remains for producer and merchant to sit down across the table and determine how to eliminate sources of friction when they exist, and to examine ways and means of furthering their mutual interests.

To illustrate co-operation or the lack of it, I can hardly do better than cite a few instances which have recently come under my personal observation.

Prices and complete information should be promptly given. There is no warrant for the assumption that because a customer is some thousands of miles away there is no hurry about quoting. Delay may readily result in business being awarded elsewhere.

Recently an inquiry was sent out for a gas engine driven air compressor. The manufacturer did not get his prices in for over two weeks. Meanwhile the business was placed elsewhere. An identical instance was in railway motor cars, where similar delay resulted in losing the business.

Not only must quotations be made promptly, but they must be complete. Frequently prices will be given with no delivery date, or with no weights and measurements. It is a waste of the manufacturer's time to offer incomplete information, for the exporter must withhold cabling at all until he has all the required data. Thus on a government tender for railway equipment prices were promptly received, but no delivery date specified. By the time this was finally given, the tender date was past, and this particular equipment was not considered.

In another case inquiries were issued for some heavy punch presses, rolls, etc. The manufacturer's reply neglected to give either the weights or measurements of the individual shipping packages, thus rendering it impossible to figure up a c. i. f. quotation. This illustrates a point that cannot be too strongly emphasized, i. e., that correct weights and measurements are just as essential as the f. o. b. price. Moreover, in measurement of cargo, the size of the package not only influences the ocean freight, but sometimes determines whether it is more economical to ship from the Atlantic or Pacific coast.

Follow the Specifications

In other respects the specifications must be followed exactly, without the substitution of something "just as good." An order was placed for steel shafting which called for 1⅝ in. diameter. On delivery about two-thirds was found to be 1 9/16 in., and was in consequence rejected. The maker, with a fine spirit of co-operation, undertook to stand the cost of making good, but he could not compensate for the loss of prestige which both he and the exporter suffered.

Another order called for a concrete mixer driven by a 5 h.p. engine and a 6 h. p. boiler. Without advising the exporter, the manufacturer supplied a 6 h. p. engine and an 8 h. p. boiler. He naturally felt that he was being very liberal in furnishing something larger and better than the order specified. What actually occurred was that the freight was higher than estimated and the buyer was dissatisfied because the outfit did not fit the foundation he had provided.

It is worth remarking, while on the subject of specifications, that occasionally neither the exporter nor his customer knows exactly what is wanted, in consequence of which the inquiry may be very broad and lacking in essential detail. In such cases it is a mistake to reply to the effect that quotation cannot be made because insufficient information has been furnished. The proper course is to offer something—whatever may seem most likely. This at least gives the buyer some ideas. He may come back and order just that, or, if not, he will state what modifications he requires.

Having covered a few of the points, up to the time the order is placed, we come to the somewhat delicate question so often touched on in these conventions that it requires some hardihood to mention the word, namely, packing. And before going further, I want to say that great progress has been made. As a rule we no longer have shipping packages dropping to pieces on the dock before being loaded. The great majority of manufacturers can and do supply very satisfactory export packing. But here again close adherence to the exporter's specifications is essential.

For example, an order was placed for some locomotive parts. The manufacturers specified that those would be shipped in two large cases. When shipment was made, however, it was found that the entire shipment had been packed in a single box. The weight of this single piece was such that additional heavy lift charges were involved, greatly increasing the estimated freight. The manufacturer, no doubt, thought he was performing a real service, in that the total weight was reduced, yet actually the total cost was materially increased.

One of the most interesting cases on record was where the exporter received an order for old newspapers, baled, and bound up with red iron straps. This was passed on to the suppliers exactly as received, with the wording: "red iron straps" underscored. Shipment was made as requested, except that the bales were bound up with black iron straps. On arrival at destination payment was refused, solely because of the color of the straps. It appeared that in this particular market red bands had been used for years, and had assumed the proportions of a trade mark, so much so that anything else was regarded as an imitation. The supplier, by the way, refused to make good, and the exporter had to sell the shipment elsewhere at a considerable loss.

In another case certain material was supplied which, because of its character, hardly required any packing at all. The manufacturer, however, for good measure, put it all in barrels. On delivery to dock these showed slight signs of breakage, enough at least for the steamship company to endorse on the bill of lading "barrels frail." In such cases if loss were discovered on delivery, the steamship company could not be held liable, because it had given the

shipper a receipt, not for so much material, but for so many barrels, and had specifically called attention to the frail character of these.

It must be emphasized that packing estimates, i.e., weight and measurement, must be as accurate as circumstances will permit, and not merely figured with large factors of safety. Thus in checking up a large supplier, it was found that his packing was always well within the weight and measurement promised. The result was, of course, an actual saving in freight estimated, but the manufacturer had failed to realize that c. i. f. quotations on his material were always high, by just that much, with consequent risk of loss of business to competitors.

Exchange Information

Let us now turn to one or two other phases of the situation.

A manufacturer of a popular specialty unloaded many thousand dollars worth of stock, held abroad, on his agent, just before putting a new and improved article on the market, selling at the same price.

Co-operation between manufacturer and exporter should largely take the form of constant interchange of information. Advance notice of new designs, improvements, etc., greatly strengthen the exporter's ability to get business. Sales helps, such as suggestions for new uses of material, advantages and adaptability to certain conditions, in a word the same sort of data supplied local salesmen, are eagerly sought by the exporter.

Foreign advertising should be done by the manufacturer, but generally in consultation with the exporter. Useful energy is wasted when a supply of literature in Spanish is forwarded to Yokohama (an instance which recently happened). Nor is there much use in advertising a device for thawing out frozen water pipes in a publication having its principal circulation in India. Furthermore, it is not quite reasonable to ask an exporter to do all the advertising in his district out of his comparatively meagre commission. I would venture the opinion that most costs on which export prices are based include, along with other overhead, the total cost of domestic advertising. Should not some of this be allotted to the foreign field?

And this brings us to another closely related point. Does not the average so-called commercial cost of an article generally consist of the bare factory cost of labor and material plus a percentage running all the way from 50 per cent. to perhaps 150 per cent to cover so-called "general overhead?" And does not this "general overhead" consist, in large measure at least, of the cost of traveling salesmen, branch offices, entertainment, not to mention domestic advertising and miscellaneous selling costs, solely arising in the domestic market? At the risk of unlimited condemnation, I venture the opinion that foreign costs should be figured on a materially lower basis than domestic, and that foreign buyers be given the benefit thereof.

The foregoing gives an indication of some of the means whereby greater co-operation will lead to better results. It is, however, only fair to state that there are a very large number of cases where perfect understanding and accord prevail, and where, if the exporter fails to secure and hold business, it is not the fault of the manufacturer. Without taking the time to cite any large number of these, a few typical instances stand out, and are worthy of special mention.

Create Good Will

A large manufacturer of tin plate received an order for a considerable shipment at a time when prices were still high. Subsequently the exporter requested that delivery be postponed. Meanwhile price declined. To insist on shipment would have meant a heavy loss. The manufacturer not only held the goods, but when shipment was finally made adjusted the price to conform to the then existing market. The good will created with both the exporter and his buyer in the long run will make up many differences in price.

A motor car manufacturer had shipped a number of cars to China, and was aware that his agent had on hand fairly large stocks. A price reduction was put into effect, and the agent notified that he would receive an equivalent rebate on all cars paid for but not sold. A manufacturer of gas engines did precisely the same thing, though the original shipment had gone forward a year previous. They may both confidently look forward to increased and sustained business.

A manufacturer of lead pencils received word that his product was being offered by unauthorized dealers in his agent's territory. He promptly investigated, stopped the source of supply in this country, and went to extraordinary effort to protect the interests of his representative.

A maker of boilers and radiators has such confidence in his agent's representations that, when he receives advice of particularly close competition, he adjusts the price to meet it, being well satisfied.

One of the principal railway suppliers constantly maintains its own representative in the foreign office of the exporter, not to attempt to do business direct, but to supply technical information and assist in securing business. Others are following substantially this same procedure, and the exporter welcomes the presence of such representatives, and affords them every facility.

BOOKLETS

The Athol Machine & Foundry Co., of Athol, Mass., have just issued an interesting little catalogue, No. 35, covering the range of vises and grinding equipment manufactured by them. A section at the back is devoted to a detailed reference of parts, so that replacements or repairs may be quickly obtained by ordering by part numbers.

PUNCH PRESSES AND WHAT THEY CAN ACCOMPLISH

(Continued from Page 35)

goes between the two short angles and as the ram descends, the fingers shown at A, drop down and grip the stock. As the ram ascends, the spring B, forces the fingers back allowing the operator to remove the material. This same idea can be used on other work of extreme length where the stock is thin and must lie down to the gauge point without trouble.

The future possibilities of press work are almost without limit. We now have presses stamping and forming parts which a few years ago were considered casting propositions. At one time door knobs were made from castings, but now the press stamps a steel disc out of a large sheet, draws the disc to a cup shape, bends it over and makes one half of the knob. The other portion is also formed in the press and a spot welder fastens both parts together. Thus, we have a lighter knob, a more economical one, and a smoother finish to the complete article. Of course in some cases, knobs are made without spot welding but this explains one method only.

What holds true of doorknobs is likewise true of thousands of other parts. The toggle drawing press has allowed operations to be completed which were unthought of a few years ago, until we now have large automobile parts drawn on these presses, where before hand work was necessary in the great majority of cases.

The piercing of armature discs is another operation which the press has mastered successfully. Imagine piercing 7,000 discs per day from 27 gauge steel, 19½ inches wide, yet this production is being secured daily in one large plant.

Then we have the variety of household utensils, which are procurable at the store at comparatively low prices. Again the press is the answer, for now the drawing of open hearth steel is made possible through the use of such modern machines. We might refer indefinitely to work produced on this type of machine but it is sufficient to mention only a few. Automobile lamp shells, railway gongs, cow bells, automobile parts of all kinds, keys, roller bearing parts, agricultural implement parts, oil stove bases, washers, electrical parts, telephone parts, cans and in fact almost any shaped piece made from sheet metal or sheet steel.

Of three tenders submitted for the construction of the proposed street railway extension to Chippewa park a distance of one and a third miles west of the city, one of $8,100 was the lowest. The city council believed the bid too high and new tenders will be called for. Much of the material for the construction of the road will be supplied by the city.

Theory and Practice Should Go Hand in Hand

When Fault Arises Eliminate the Cause—All Conditions Subject to Fixed Natural Laws—Technical Trained Man Better Able to Reason Out the Cause of Trouble and Remedy Defects

By JOHN S. WATTS

A HABIT that is well worth forming, particularly so with people who are engaged in the manufacture and use of machinery, is that of always striving to understand the cause of all those happenings which affect their work. This may be better understood by stating that it is the opposite to the all too common habit of being satisfied with knowing that under certain conditions, such and such a result will occur, without a full knowledge of the reasons why it does so, or of what will be the effect of a slight change in the conditions.

That many of us are guilty of being too lazy to use our brains to avoid minor difficulties can be proved by observation of our conduct when matters are not progressing normally. Consider for example, the average man running a lathe, if the belt slips off the pulley, he will put it back, ad unless this slipping is repeated at such short and frequent intervals as to render it impossible to make any headway with the work he will be satisfied to simply replace the belt as fast and as often as it slips off. When it becomes imperative to do something to stop the belt from coming off, it is common to do the easiest and most obvious thing namely, reduce the cut until the belt will drive, without studying the conditions to determine whether the belt is really over-loaded, or if it is prevented from delivering the power it is capable of by reason of slackness, mis-alignment or other cause. Similar examples without number can be cited by anyone from their own observation, indeed the practice of merely starting off again after a mis-hap, without attempting to find its cause and so arrive at the means of preventing its recurrence is so common as to have become a fixed habit with almost all of us, which is possibly what led the poet to say "hope springs eternal in the human breast."

Granted that there are occasions upon which it is impossible owing to pressure of time, to stop for an investigation of the cause of the mishap, it is in the great majority of cases a saving of time to do so. In any case an effort should be made to discover the cause even if only after the accident has been repaired, for the sake of preventing its recurrence later on, as unless some action is taken, the same conditions are practically sure to be repeated some time, with the same result. At the same time, we should not confine our studies to those cases only where trouble has resulted, it is just as, if not more, important to know the reasons why a certain method gives effective results. While it is good to know that certain actions will produce a certain result, this limited learning, if unaccompanied by accurate knowledge of the laws of nature which are responsible for the result gained, will never help much to enable us to accomplish similar results by more efficient means.

Forecasting Results

The so-called practical man, whose knowledge of what can be done, and what cannot be done, is limited solely to that which he himself has achieved or seen others accomplish, is apt to consider all knowledge that has been gained otherwise than from personal execution of work as purely theoretical. This attitude is based upon a misconception of the true state of affairs, seeing that every event that occurs in this world is caused by effects which are subject to unchanging laws of nature and that if we know and understand the laws that control a given set of forces we can forecast exactly what will be the result of their application under any given circumstances.

The practical man will pride himself on knowing by actual experience such matters as that a certain size of belt will drive a certain machine, but if called on to decide what size of belt should be used to drive a similar machine of a different size, will have to guess at it, because he has no real knowledge as to why the belt in the first machine was able to do the work. That is, not being familiar with the laws which govern the action of a belt drive, he is unable to say whether, to deliver say double the power, a certain belt should have double the thickness, or double the width, or if some other combination of width and thickness of belt would be better. On the other hand a man who by education or by his own observation and reading, has mastered the basic laws of the subject, would, even without the experience of the practical man with the first machine, be able to calculate the size of belt to use on the new machine, from a study of the conditions to be met. If the educated man had the same experience as the practical man had, his calculations would of course be based upon the performance of the belt used in the first machine and would be that much more dependable, because there are in all problems relating to mechanics certain factors, such as friction etc., which cannot be exactly pre-determined, except from experience with similar machinery. Nevertheless by reading the technical publications we can practically always find some data bearing upon these indeterminate factors, the use of which will permit us to forecast the requirements sufficiently close for all practical purposes.

Torsion of Shafts

Without such knowledge of the laws of nature, a man is very apt to make many errors in basing answers to new problems on experience with other similar work. From several examples, I will quote only one instance, where a shaft being required to transmit double the horse power of the one then in use, and at the same speed, a shaft having double the area of the old one was installed. The torsional strength of shafts varying as the cube of their diameters, while the area varies as their squares, the new shaft was really capable of delivering 2.83 times the horse power of the old one. Further the original shaft had been made larger than was required to transmit the horse power as it had to support the pull of belts located away from the bearings. So that, as a matter of fact the new shaft did not need to be even twice as strong in torsional strength.

Undoubtedly the man who has studied the laws of mechanics, being human, does also make mistakes, but mainly through not having at his command as much experience as the practical man, he is apt at first to give insufficient weight to some of the factors that experience alone can determine. But he has the advantage of being able to study out the reason of the failure, and in the end has gained knowledge through his mistake, whereas the practical man, is seldom any wiser than before, particularly as he generally errs by making his mistakes on the safe side so far as strength is concerned. This however leads to failure on the commercial side when in competition with some one who can accomplish equal results with less material. It would help the practical man to dissipate some of his assumed contempt for theory, as he mis-calls knowledge acquired by study, if he will consider how this knowledge is gained. The various laws of nature have been determined, are not as he thinks, purely theoretical using the word in its true sense, that is that a theory is some statement that is in all probability true, but which cannot be absolutely proved. On the contrary almost every known rule is based upon actual experience, and has been determined by working tests, and proved over and over again in use.

Rectangular Beam

For example the fact that a rectangular beam on edge will carry a much greater load than it will if laid upon its side, as a matter of common experience, and was undoubtedly known centuries before the beam formulae were worked out. All that the students of science have done was to determine by study, and experimental tests the exact relationship between the

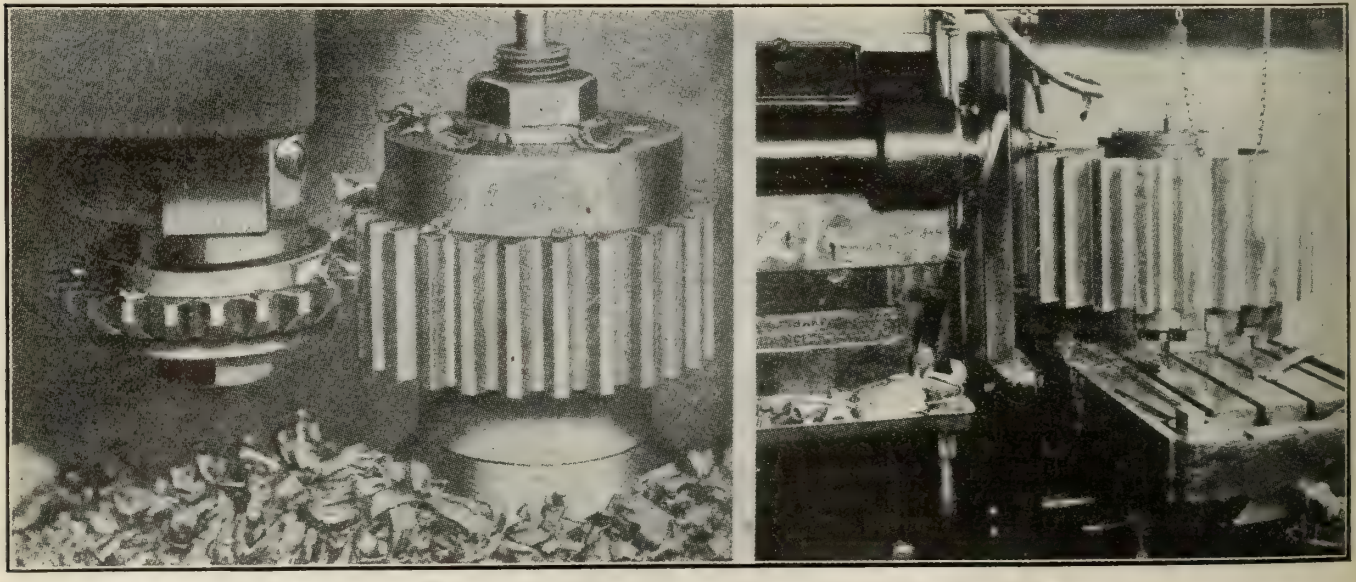
Geometric Control of Gear Cutter Movement

Careful Grinding of Cutters is Necessary to Maintain Proper Shape—Using the End Mill Type of Cutter—Machines for Cutting Double Helical Gears Are of Special Design

By CHESTER B. HAMILTON, Jr., B.A.Sc., M.E.

WE ARE here continuing the description of the different methods of forming gear teeth, as outlined in our issue of May 25.

The Sellers system uses 20 degree angle, with addendum of 0.3, dedendum 0.35 and clearance 0.05 of the circular pitch. The Fellows system is the most modern and in many ways the best in results, though it is argued against it that it has no fixed ratio of pitch and addendum. It is used in nearly all automobile spur gears and is pretty well established as the standard for generated spur gears, that is, those cut on the gear shaper or the hobber. In this system the pressure angle is 20 degrees and the addendum varies from 0.264 to 0.226 of the circular pitch. The pitch is given in terms of diametrical pitch and is written as a fraction, the numerator specifying the diametrical pitch from which it takes its tooth thickness and space width. This pitch is calculated in the usual way, being the number of teeth per inch of pitch diameter. The denominator of the fraction gives a finer diametrical pitch which governs the addendum, dedendum and clearance according to Brown & Sharpe proportions. That is a 6/8 pitch Fellows stub tooth gear has the same pitch diameter, tooth thickness, space width and circular pitch as the six diametrical pitch Brown & Sharpe gear of the same number of teeth, but has the addendum, dedendum and clearance of an eight pitch Brown & Sharpe tooth. The Fellows' pitches are 2-2½, 2½-3, 3-4, 4-5, 5-7, 6-8, 7-9, 8-10, 9-11, 10-12, 12-14, 14-18. The standard Fellows machine will not cut coarser than 3/4, but heavier pitches even than shown above can be cut on large hobbing machines to the same proportions.



The Stub system is not so largely used for bevel gears as for spurs, for the single reason that bevel gears with shafts at right angles do not belong to an interchangeable system, being made in pairs and to run with none other than the mate originally laid out. This being the case, the long and short addendum method of preventing under cutting and interference is perfectly feasible, and is better in giving a smoother action at the high ratios used in automobile rear axles. There is a slight sacrifice in efficensy in the longer flank, but not serious, and it is outweighed by the advantages. The Gleason templet type of bevel gear shaper uses templets of any pressure angle desired, and on those of low angle there is a correction to prevent under cutting after the same manner as in the Brown & Sharpe system.

There are three ways of producing the tooth curve. The first method may be copied from the actual form of the cutting tool by direct contact in the act of cutting. Second, it may be copied from a templet, which is attached to the machine to guide the cutting tool in a suitable path to describe the required curve. The form of the tool in this case does not resemble the form of the work. The first way is most used for small work, and the second for large. The third, and most modern way, is to generate the curve of the tooth by certain geometric motions of the machine which control the action of the tool (or tools) in a way to cause its cutting edge to describe the required tooth curve on the work, as well as move in the direction to cut away excess metal. The tool and the work nearly always have relative motion in three dimensions, and sometimes a fourth motion is introduced, as for indexing from tooth to tooth.

Circular Milling Cutter

The circular milling cutter with its edge formed to the size and shape of the tooth space is the commonest tool for cutting gears. The periphery of the cutter is relieved, or "backed off" from the cutting edge in a spiral curve, so that the face of the cutter can be repeatedly ground to sharpen it without changing the profile. The grinding is radial on finishing cutters, though not necessarily so on stocking cutters used on coarse pitches to do the heavy preliminary work of roughing out the slots. These cutters may be used in a variety of machines ranging from the common milling machine with dividing or indexing head on the table up to such highly specialized forms as full automatic rack cutters. The standard type of automatic gear cutter is produced in a variety of sizes by such firms as Brown & Sharpe, Gould & Eberhardt, Cincinnati Gear Cutting Machine Company, Flather Manufacturing Company, and Whiton Machine Company.

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Member of Canadian Engineering Standards Association.

Left.—Cutting gears in a Fellows gear shaper. Right.—Cutting gears with end mill.

Helical gears can be cut on a universal milling machine by using the "spiral feed" through the dividing head, but in such work one is confined rigidly to gears of the normal circular pitch for which cutters are at hand, and as explained in another section, the centre distance of the two gears must then be made to suit the gears which can be made. With a generating process the pitch can be adjusted by enlarging both blanks proportionately.

Bevels and Worms

Bevel gears can be made with a rotary cutter, but not good ones, nor with even an approach to correct theory. A skilled man with a special narrow pointed cutter and a universal milling machine can, by the "set over and roll" method make a gear that ran be filed into shape with not too much hand work, but this is not gear cutting.

Worms can be milled with a single formed cutter, which requires to be specially made for the job, as mentioned in another section, on account of interference of the trailing edge of the cutter with the finished side of the thread on one side. Worm wheels cannot be made with a rotary disc formed cutter, nor can spiral scrolls, nor spiral bevels.

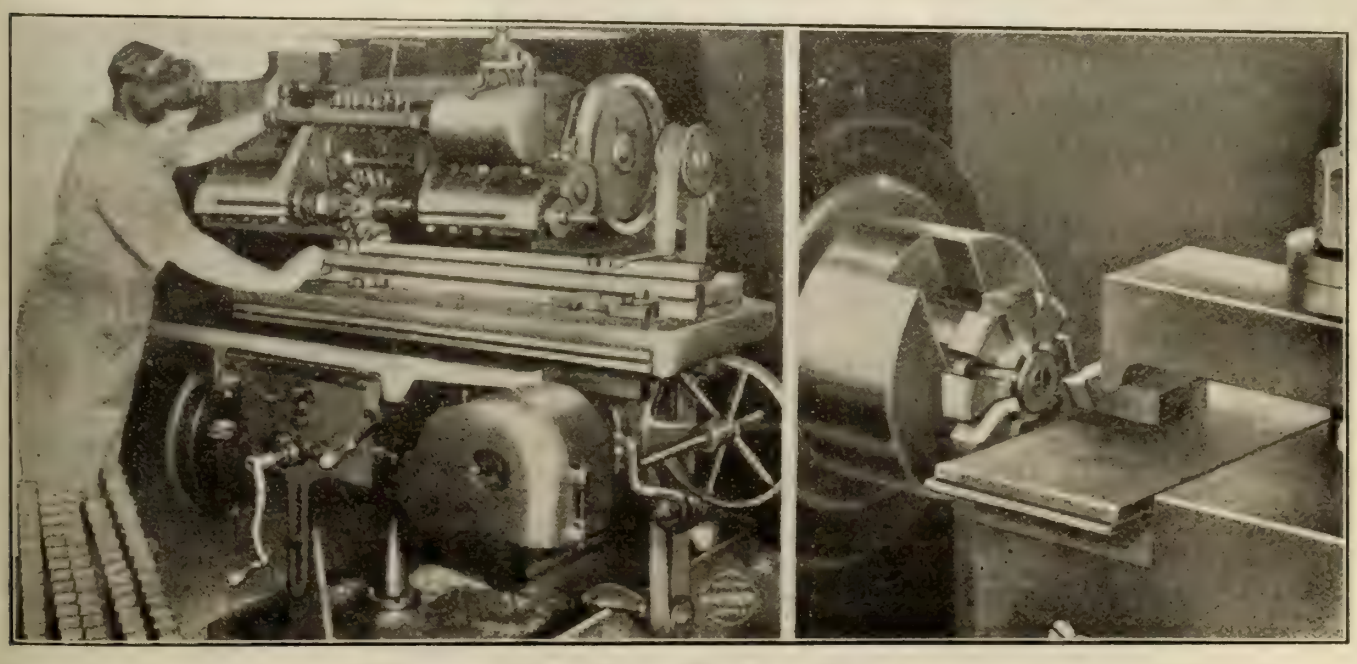
End Mill Cutter

The second class of formed tool for gear production is the end mill. The longitudinal section of the tool, which includes its axis, shows the profile of the gear tooth space. The tool axis is perpendicular to the work axis, and it is fed parallel to the work axis along the tooth space. The end mill may be a solid fluted tool or have inserted blade cutting edges. This process is adapted to cutting heavy spur and double helical gears, the latter having been highly developed by Andre Citroen, at Paris, France. He has also cut bevels by this process, but their correctness is very doubtful. The quality of spurs and helicals by this process is good, but the rate of production not as high as by other methods.

Reciprocating Cutters

The third class of formed tools includes those having a reciprocating motion, parallel to the axis of the gear. In this class are the slotter or shaper tool, now little used; the broach, used for planing the teeth of internal gears, and the punch and die for stamping small gears either external or internal, out of sheet metal. All of the above refers to spurs.

Template Control of Cutter



The second general method of producing the tooth curve is by copying it from a templet which controls the path of the cutting tool. Generally the gear cutting machines employing this method are of the shaper, planer or slotter type. The tool is an ordinary straight or forged planing tool with the cutting edge at the tip rounded to the same radius as the fillet at the root of the gear tooth. Then the point where the straight side of the tool is tangent to this curved end may be considered the describing point. Tools are cut with side rake and are right and left hand, and the templets are convex and concave to work on the upper and lower curves of the tooth. The process is applicable to spurs, bevels and double helical gears in medium and large pitches, and in the case of bevels there is a Gleason machine which will work down to quite small pitches. In the bevel machines one end of the tool carriage guide is mounted on a double pivot construction, the two axes intersecting at the cone of the machine, so that the guides may swivel universally about the centre point.

The length of the tool is fixed by gauges from the guide, so that the describing point on the tool always travels exactly towards the cone centre. The other or outer end of the guide carries a roller which rides on the curved templet, the centre of the roller traversing the tooth curve on a magnified scale. The Gleason machines are the best examples of the spur bevel planers. The Newton is perhaps the best known of the vertical slotter type, although these are not common. The larger Gleason bevel machines are universal and can be used to plane spur gears by swinging the guides to a position parallel to the work axis, and changing the tool carriage. Arranged in this way the machine will plane internal as well as external spurs. The machines to plane double helicals are of specialized construction for this work, and are used almost exclusively for heavy rolling mill gears, and especially mill stand pinions which are of very coarse pitch.

Range of Cutters

On all formed tool and templet work, account must be taken of the fact that the form of the tooth is not the same for gears of different numbers of teeth. In the Brown & Sharpe system eight different cutters are supplied, each of different shape, and each covering a portion of the range from a twelve tooth pinion to a rack. In the Templet system, the Gleason bevel machines have twenty-five pairs of templets covering the range from a pinion of small pitch angle to a gear of large angle approaching a crown gear. The thirteenth templet is for mitre gears of one to one ratio. It is to be noted that with spurs the selection of the cutter is according to the number of teeth, while with bevels the selection of templets is according to the pitch angle, or, what is the same thing, the ratio of the pair. This is because the shape and action of the teeth in a bevel gear depend not on the number of teeth in the gear itself, but upon the number there would be in a spur of radius equal to the back cone radius of

(Continued on Page 48)

The Proper Heating and Cooling of Steel

Less Trouble Experienced With Small Masses—All Portions of a Piece Should Be Subjected to Same Temperature—Human Element the Weakest Link—Temperature and Time Most Important Factors

By JOHN A. SUCCOP

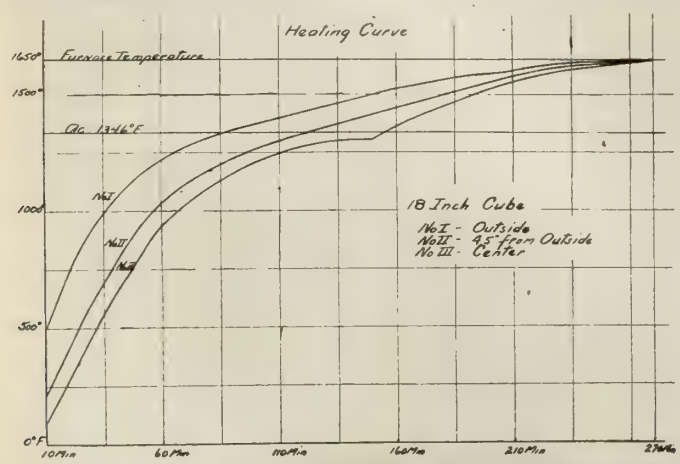
ONE of the most important sciences in the mechanical field to-day, and one which necessitates the most careful and skilled application of its principles, if correct results are to be obtained, is the heat treatment of steel. There are certain fundamental facts which are worthy of attention. Of these facts, one of the most important is uniform results, which minimizes the possibility of low standard work. Uniform results are obtained through proper heating and cooling, and proper loading of the furnace charge. Less trouble is expected with small masses, for they do not present the same difficulties that are encountered with large furnace loads. It is well known that the molecular changes which occur in steel are not fixed and unchangeable, but depend on both the temperature at which they take place and on the duration of time of changing, upon the rate of cooling and the initial temperature to which the steel has been heated.

It is generally assumed that the proper heat treatment of steel requires nothing more than a uniformly heated product; that a uniform product requires nothing more than a uniformly heated furnace; and that a uniform pyrometer record assures a uniformly heated furnace; consequently, a uniformly heated product within that furnace. When the pyrometer rod is used in a heat treating furnace, it should be so placed that by looking in the furnace door, a direct comparison can be made by the eye as to the temperature of the charge with the temperature at the end of the rod. The pyrometer rod should never be hidden from the eyes of the operator unless the couple be buried in the center of the material and protected from the flames.

Frequent Variation

From the study of metallurgical results of the finished products, heat treated in an indicated, uniformly heated furnace, we find that a variation frequently is found. There is a greater problem to heat treating than the maintenance of a uniform temperature in the heating furnace. These variations are not confined only to furnaces of different types, for the variation is found in the same furnace, the pyrometer readings being the same in each case. Such variations are brought about by the position of the load in the furnace and by a difference in the heating of the load.

The best test of the uniformity of a heat treated piece of steel is the manner in which the load cools, for it is the uniformity of the steel as it passes through the critical range and takes its final and permanent set, that gives to steel the results of the heat treatment. To heat uniformly, it is necessary that each piece be subjected to the heat in the same manner, at the same temperature, and for the same length of time in proportion to the size of the section.



If a large amount of material is placed on one end of the furnace charge, it is likely that the outside pieces will be heated to and cooled from a higher temperature than the pieces at the centre of the mass. Likewise with cooling, if a large mass is plunged into a quenching tank, there is a tendency for the temperature of the bath to become irregularly heated and also for the outside of the mass to cool at a different temperature and in a different period of time than the centre.

Effect on a Large Mass

With large masses it is unreasonable to suppose that each portion of the section receives the same amount of heat that the other portions received, and that it is subjected to the same heat treatment. Unless all pieces are heated and cooled exactly alike, the pyrometer indications of uniform temperature serve merely as evidence, but cannot be accepted as proof of a uniformly heated furnace, or a uniformly heat treated furnace charge, or a uniformly heat treated product, as a final result. There should be better appreciation and understanding of the difference between a pyrometer record, which indicates a uniform temperature and of the conditions which bring about the uniformity desired in the furnace.

The following is a quotation from Dr. Howe in his book, "Iron, Steel and Other Alloys." "You cannot make a bad beefsteak good by the cooking; you can cook it better or worse, and it will be a worse or less bad beefsteak, but always bad. On the other hand, you can easily spoil a good beefsteak by bad cooking. Now, just as cooking is to food, so is heat treatment to steel. Indeed, a pedantic cook might reasonably call cooking, heat treatment." This simile of Dr. Howe's is right to the point; for the application of heat to industrial material is but a cooking operation, like the cooking of food or the baking of bread; each must be thoroughly done—that is, it must be heated uniformly to the centre. To cook or heat to the centre with the temperature being equal from the surface to the

Paper presented by the author at the May sectional meeting of American Society for Steel Treating at Pittsburgh. Author is associated with the Heppenstall Forge and Knife Co.

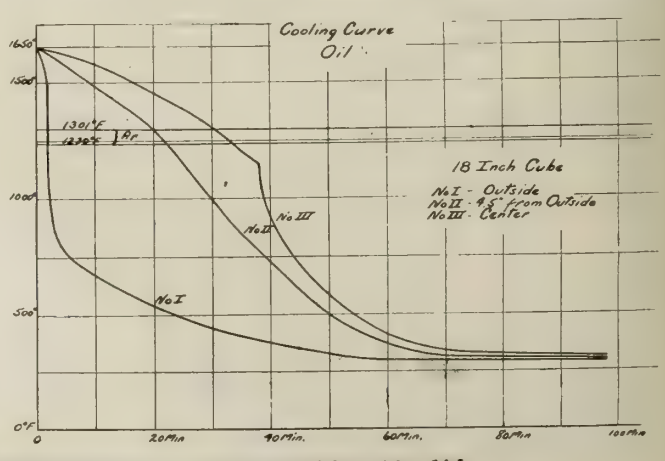


Fig. 1.—Left; curves representing the heating of a steel block 18 in. sq., showing rapidity with which heat penetrates the centre of mass. Fig. 3.—Right; curves representing the cooling of a steel block in the furnace. The cooling takes place slowly.

centre requires a slow fire and time in proportion to the amount of material to be heated. Overloading, as well as improper loading, will prevent the proper circulation of heat, and it is likely that a part of the charge will rise to the desired temperature in a non-uniform condition, and will cool with even less uniformity than it heated. The indicator on the outside of the oven does not tell the story of the food being well done. This is accomplished by observation of the material.

The Human Element

Even with all our modern present day practice and equipment we must take into consideration the importance of the human element. The heat treater, although the weakest link in the chain of perfection of the product, is the one that puts the metallurgical finish on the material at a great expense to others, and it is the skill and judgment that either perfects or spoils the material. Have we not all heard of the manufacturer who thinks he is protected from all the evils of heat treatment because he has the best pyrometer system that money could buy, with automatic recorders in the office, so that at all times, he knows the condition of the furnace and what each heater is doing? Besides this, he has a man whose sole duty it is to watch these instruments and the temperature recorded on the pyrometer, and to indicate to the operator by a red, green, or blue light just when his temperature is low, high or just right. He is sincere in his belief and he thinks he knows what good heat treating is, but his standard is low, due to the reasoning that a uniformly heated product requires only a uniformly heated furnace, which reasoning leads to the development of the pyrometer to indicate the uniformity of the product.

This is all right as far as it goes, but it does not go far enough, for it may be an indication of the temperature of that particular part of the furnace, but it surely is not proof that the product in the furnace is at that particular temperature, as indicated. The proof for this statement is the trouble we encounter with variations in the finished product, although the pyrometer chart gives no indications of a temperature variation. The uniform heating of a furnace and of the product within that furnace are two entirely distinct operations, and while the former must accompany the latter, yet the former does not prove the existence of the latter. The final conclusion of this analogous reasoning is that it is neither logical nor conclusive, and the actual results all hinge on the experience and knowledge of the man at the furnace.

Skill of Operation

There are a number of elements that directly affect heat treatment. They are not indicated by the use of pyrometers or other heat determining devices, whether mechanical or electrical, but are determined by the judgment and skill of the operator at the furnace, as the cook judges the quality of the food baked in the oven.

When the pyrometer indicates the desired temperature, what determines when the charge in the furnace is completely saturated?

What determines proper loading conditions as regards to mass heating and gas circulation?

What determines when the temperature of the bottom of the mass is equal to the temperature of the center, and when the top equals the sides?

What regulates the flow and combustion of the fuel into the furnace, causing an oxidizing, reducing, or neutral action?

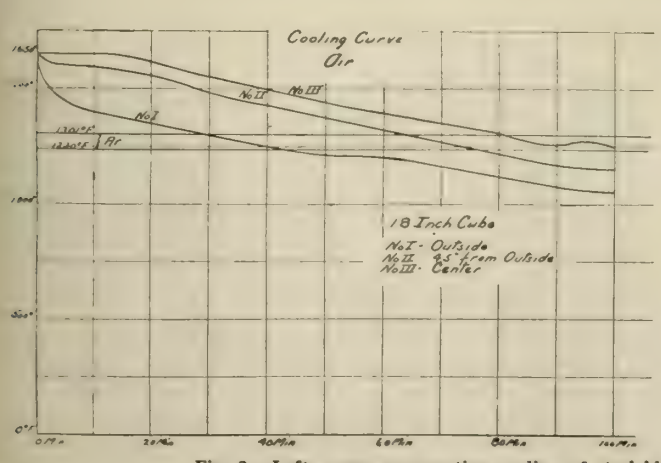
What regulates the uniformity of each piece, compared with each other piece in the charge that they might all be treated the same?

The four factors which govern the heating and cooling of all material, whether it be food or an ingot of steel, are temperature, time, surface and mass.

Temperature. This is the degree of heat required to produce the desired molecular structure and grain size.

Time. This is the period required to saturate the piece to the desired temperature, and to permit the metallurgical reactions to take place.

Surface. This is the area of the section exposed to the heat, which influences the rate of absorption, the time of soaking and the uniformity of the piece.



Mass. This is the amount of material to be heat treated, which influences the time of heating and the time of saturation and uniformity as well as the manner of supplying the heat.

Of these four, temperature and time are the important factors. Temperature is determined by the metallurgical effect that is desired, but time is governed by the surface and mass and also by the type and composition of the material being treated. That is the time necessary to soak a piece of low carbon steel might vary from the time necessary to soak a piece of alloy steel. Soaking means the completion of the metallurgical reactions that take place upon cooling and heating the steel. Often our time for allowing the sections to become saturated is not enough and our results are not uniform. When loading, the largest surface should be exposed to the source of heat to insure the minimum time and maximum uniformity. The reverse would mean that it would be necessary to expose the surface of the mass to the heat for a greater length of time than the section at the bottom of the mass. Ideal cooling is just the same condition reversed.

A striking example of this is found in a large die block, where the corners heat and cool much more rapidly than the main body of the die. Every possible effort should be made to prevent overheating the corners, or exposing them to the extreme final temperature any longer than is absolutely necessary. This might be accomplished by thoroughly saturating the dies at a temperature slightly below the final temperature. The corners of a die, because of the greater surface, heat first and cool off first, and cause an unequal expansion and contraction in the steel.

Study of Curves

The effect of mass on the heating and cooling of steel might be clearly shown by a study of the curves developed by Law. These curves are produced under as ideal a condition as possible, and they represent the changes that are found in

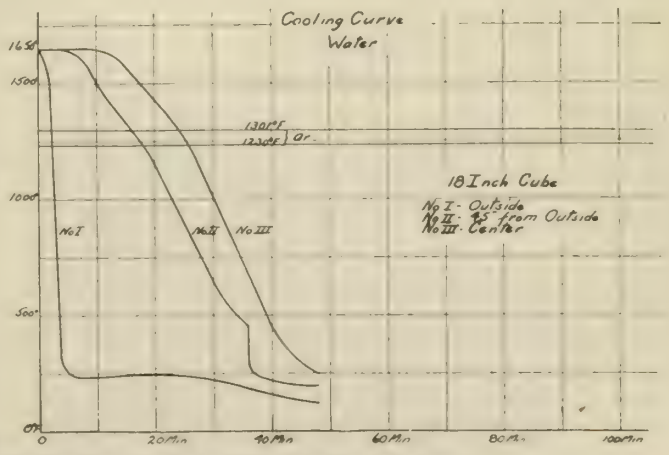


Fig. 2.—Left; curve representing cooling of steel block in quenching oil, the rapidity of cooling being due to large volume of oil and its rapid circulation. Fig. 4.—Right; curve of steel block heated to 1650 deg. F. and cooled on knife edges by a high pressure water spray. Cooling is more rapid than in water quench.

a large mass of steel during the heating and cooling. The curves were developed by the followig means: Eighteen-inch cubes were forged from a 25-inch ingot, only the soundest part of the ingot being used. The thermocouples were inserted into the cubes to be treated—one in the center; 4½ inches from the center, that is midway between the center and the outside; and one ¼-inch from the center of the surface.

Fig. 1 represents the heating of a block of steel 18 inches square, and shows the rapidity with which the heat penetrates to the center of the mass. The center and outside temperatures approach each other before going through the critical range but at this point, the absorption of heat due to the change causes a greater lag at the center than anywhere else, and the two temperatures fall away from each other for a period of time. However, after being in the furnace for about 4½ hours longer, the cube attains a uniform temperature throughout its mass, and practically coincides with the temperature of the furnace.

Fig. 2 represents the cooling of a block in the furnace. These curves require no explanation. The cooling takes place slowly and as in the case of the heating curves the evolution of the heat is most marked in the center of the mass.

Fig. 3 represents the cooling of a block in quenching oil. The rapidity with which the block cools in the oil bath is due to the large volume of oil and the rapid circulation.

The block shown in Fig. 4 was heated as before to 160 degrees Fahr. and cooled on knife edges by a high pressure water spray. The block, as would be expected, cools off more rapidly than the oil quench. The curve also shows an evolution of heat in the center. Attention is called to the abrupt halt in the cooling at about 250 degrees Fahr. It is hardly likely that this halt is caused by the water getting into the thermocouple hole, because the temperature remains constant for so long a time, and at 50 degrees above the temperature of boiling water. Experiments repeated on various sizes of blocks show that the phenomenon occurs with remarkable regularity and is not affected by mass.

The existence of a low critical point has been verified by a large number of scientists, and if proved correct, will throw a new light on the phenomenon of hardening in steel.

Essential Features

Law sums up the essential features of the curves as follows: "The extreme slowness of air cooling as compared with either water or oil cooling, is too obvious for comment. A comparison of the curves obtained by oil and water cooling, is of great interest. The important difference between the two methods of cooling is to be found in the almost sudden slowing up of the cooling in oil shown in the lower ranges of temperature, as compared with the cooling in water. For example, the time required for the center of the cube to cool from 1650 to 1000 degrees Fahr., a temperature well below the critical range, is almost the same whether oil or water is used as the quenching medium. In cooling from 1000 to 600 degrees Fahr., however, the cube cooling in oil requires twice the time, and in cooling from 600 to 300 degrees Fahr., it requires nearly four times as long. The differences are even greater on the outside of the cube. The oil cooled surface takes six times as long as the water cooled surface to cool from 600 to 300 degrees Fahr. It may be observed with interest that both in oil and water cooling, there is a period during which the metal in the center of the cube is cooling down more rapidly than the metal midway between the center and the surface."

These factors hold good with a furnace loaded with both large and small pieces where, in order to cut costs, the load is heated according to the perfection of the small pieces. Although the initial costs are increased, the best results are obtained by heating according to the largest section, which undoubtedly will pay in the end for the additional time necessary, but an ideal condition would be to heat treat as nearly as possible, loads made up of parts of uniform side.

The practice of heat treating without regard to the mass and surface and with an eye only on the record of the pyrometer, will always produce a nonuniformly heated product. The mass should be heat treated and not the pyrometer. The pyrometer does not indicate anything concerning the temperature of the mass, but only the temperature of the portion of the gases in the furnace or the material with which it comes in contact.

Proper consideration must be given to the human element involved. Those in charge should be educated and should in turn educate those within their charge, for upon them lies the future of subsequent operations.

From the foregoing discussion, the following conclusions might be drawn:

1. That a uniformly heated product requires more than a uniformly heated furnace.
2. That material cannot be heat treated satisfactorily when the record of the pyrometer is the only guide.
3. That the human element plays an important part in the proper heating and cooling of steel.
4. That great care must be exercised in the handling of steel to insure proper thermal expansion and contraction. This is secured only through proper loading, charging at a low temperature, and by slow firing.

Another division of the General Motors Corporation has located a factory in Canada. This concern is the Delco-Light Co. of Dayton, Ohio, and the Canadian plant will be started at Oshawa in conjunction with other activities of the General Motors. The new firm will be known as the Delco-Light Co. of Canada. R. L. Meyers will be the manager of the Canadian branch.

THEORY AND PRACTICE

(Continued from Page 39)

width and depth of a beam, and its strength of such a beam varied as the square of its depth, and directly as its width. Further study of the problem brought out the reason why this was so, and has enabled us to evolve formulae for any or all sections of beams. Hence it can be truly said that such formulae are not in any sense theoretical, but are most intensely practical and the result of actual experience coupled with a determination to understand the reason why.

The progress of the mechanical arts depends almost entirely upon the knowledge gained in the attempt to study out all the reasons for all occurrences, as in the case of James Watt. Had he been satisfied to rest content with the knowledge that the lid of a boiling kettle was raised by the steam in the kettle, he would never have discovered the laws under which the steam engine functions. His conclusions, from the study of the kettle, may be said to have been a theory but only until the first successful run of the first steam engine.

The main point that I wish to make is that it always pays well to study until we know the laws governing the forces which we are controlling in our daily work, and that sometimes such study will bring out unexpected information of great value which would never be discovered in any other way.

WONDERFUL NEW ALLOYS

IN GREAT Britain vigorous efforts are being made to develop alloys of various metals with special properties of great usefulness in everyday life. At a recent trade exhibition held in London several examples were shown of water taps and other fittings made of a remarkable aluminum alloy discovered at the National Physical Laboratory during researches carried out under the auspices of the British Government. These taps are completely satisfactory from the point of view of the water companies, and they have the merit of being noncorrodible, retaining their polish for an indefinite period. Experiments are also being carried out with the object of replacing nickel by tin in the covering of iron plates, and these experiments are expected to lead to the production of a rustless plate which will be of immense benefit to the industry all over the world. A certain nickel alloy which has great stain-resisting qualities is now being made in the form of spoons and forks and many other articles of household utility. Stainless steel knives have also been developed a step further towards the ideal. Hitherto, stainless steel has been somewhat lacking in elasticity, and a new form has been brought out in which a knife blade can be bent almost double and will spring back into its original shape instantly without its quality being in any way impaired.

Using the Camera to Help the Machine Shop

Sketches Are the Universal Language of Machine Shops—First Cost of Electric Blue Print Outfit is High—Taking Photographs of Originals for Distribution in the Plant Satisfactory Method

By ROBERT MAWSON

DRAWINGS are now used universally in almost every machine shop in the world to convey the ideas of the engineering department to the manufacturing plant. During the past 15 years the writer has visited hundreds of machine shops in various parts of the world, and during this period only one shop that I went to was doing the work in the shop without the use of drawings, it might be said this concern made only one type of machine and the workman was supplied with a sample to work from. Though they arrived at the desired results by this method I often thought that drawings would have been a much better method especially when new men were placed to work in their shop, and I have been informed that recently they have engaged a draftsman and are now preparing drawings to the parts to be machined and assembled at the plant. Better late than never.

It might well be said that drawings are the universal language of the engineer; what books are to the reader so are drawings to the engineer and machinist—a necessity. Of course there are quite a variety of drawings, from the rough sketches on brown paper in the small back-woods' town to the rather complicated perfectly designed and worked out details of the large up-to-the-minute manufacturing establishment, of which we have many. However, in all of these there are some objections to the using of drawings in the shop in the usual manner. I refer to the making of blue prints, which are sent out to be worked from. First, there is the making of the prints. This requires sushine, if a sun printing frame is used, hence no sun no print, except by a long exposure to the light.

If the more modern method of printing by electricity is used, equipment is expensive at first cost, and afterwards the cost of current to operate the machine must be taken into account. Some concerns send out their work to be printed by firms who make a specialty of this matter, but this often entails waits and at best is not quite satisfactory. A print is wanted at once and it must be sent out and often a day is lost waiting for the print.

Another disadvantage is the large size to which drawings are often made and when the prints go to the shop they are folded and creased; if a figure should come in the crease, as it often does a chance for error presents itself. Some plants mount their prints on tins or bristol board to prevent folding, but, owing again to their large size these present awkward mediums to help the man doing the work in the shop, often drawings being made as large as 24 x 36 in. or larger.

We recently installed a home made equipment at our plant to try and solve this problem and it has proved very successful and this is illustrated in Fig. 1. It consists of a camera A, suitable for taking a photo 5 x 7 in. with an ordinary commercial lens, as speed is not required for this work, and by closing the shutter, or stopping down as it is called the object taken can be as sharp as desired, every part being in focus. The camera is mounted and fastened to the wooden frame as may be seen by referring to the illustration. At the rear of the camera is placed a clock B, which can be purchased at any photo supply house having the entire surface of the dial to represent one minute, in other words the hand of the clock travels around the face in one minute. This however is not essential as when the camera shutter is stopped down a minute extra exposure will not make any material difference to the results obtained. At the rear is an open box or case C in which are placed a number of electric bulbs, of the small size used in any factory, the voltage of course depending on the source of electric current used, and will make no difference to the reproductions obtained. This case can be slid along the stand by means of the crank D that operates a rope attached to the under side of the case, the rope being wound around a sheave fastened to the crank shaft E.

The drawing we wish to reproduce is held to the glass of the case by means of paper clips F. We found that time could be saved in our work by placing guides and lines as at G so that when we were working on a size say 24 x 36 in. of tracing and wished to reduce it to the camera size of 5 x 7 the index pointer would be placed to an index line as shown, and of course would be indexed to another position for a different size of tracing, the reproductions being made of one size. This indexing is only a short job and once obtained, the card board slips were fastened to the frame as shown and the size of tracing or blue print to which they referred marked on them so that it was only necessary to move the pointer to the correct position for any size in question.

The final focusing of the camera to suit the reproduction is performed with the slide of the bellows in the usual manner. Lighting of the bulbs in the case is done with the switch H being in a handy location for the man to reach when making the picture. A reproduction of the tracing as shown in the frame is illustrated in Fig. 2 and shows how clearly the part is produced. We used the apparatus for quite a while on tracing work and thought this was the full extent of its usefulness, but a picture was also taken of a blue print, and the device can also be used for this purpose. Even on the blue print work the lines are more distinct than on the ori-

SLOTTING ATTACHMENT

An automatic slotting attachment which has been designed for use on a five spindle automatic screw machine has recently been perfected and is now on the market.

It consists primarily of a three-hole turret mounted on a suitable bracket which is attached to the machine by means of the bolts holding the stationary head caps in place. The saw head is mounted over the revolving head, and uses the same change gears as the machine, thus permitting any change of speed desired. The whole attachment is, of course, protected by guards.

In the turret are three sliding plungers carrying in their front ends, bushings fitting the screws, produced by the machine to be slotted, and having on their rear ends a T head. Three sliding spindles are yoked together by a spider and given a sliding motion by menas of a regular cam lever. Two of the spindles have a head with a T slot which engages with the T head of the turret plunger. The third, or front spindle, carries the ejector which slides through the plunger. The turret is revolved one third of a turn at the same time the crank shaft, which indexes the machine, revolves one. The cycle of operation is as follows: Just as the screw is cut off, the plunger carrying the bushing pushes up over the screw which, after being cut off, remains in the bushing.

The plungers are drawn back by the spindle to a stop and the head indexes, the small turret at the same time revolving one third of a turn, in which time the T head of the plunger slides out of the T slot of one spindle and into the next. At the next forward movement of the spindles, the screw is carried forward, slotted, and returned as before, while at the same time another screw is being picked up by the following spindle. At the third forward movement, the slotted screw is in the ejecting position, but instead of the plunger sliding forward, it is held back and the ejector pin passes through the plunger and bushing and ejects the screw. The cycle is then repeated. At each forward movement one screw is picked up, another slotted and another ejected. The attachment is made by the Davenport Machine Tool Co. of Rochester, N. Y., and is easily attached to all Davenport machines. When not in use it can be removed by taking out two bolts. All parts that are subject to wear, are hardened and ground. While intended primarily for slotting, the attachment by slight modifications can be used for other secondary operation work such as milling, cross drilling, burring, etc.

NEW CATALOGUE

The Diamond State Fibre Company of Canada have issued a new catalogue, No. 20, on Condensite Celoron which fully describes its properties, gives technical data, etc., and is illustrated.

Introducing

TRUMAN M. NORTON

This is a non-professional photograph of Mr. Norton, who is manager of the Canadian plant of the Wallace Barnes Co., Hamilton, Ontario, and is a busy man with no time for fancy postures.

Mr. Norton was born in Guildford, Conn., in 1879, and after completing his schooling, went on the farm. Later on he managed a farm for several years, but in 1905 became interested in manufacturing, going to the American plant of the firm he is now associated with. In fact since joining their staff at Bristol, Conn., he has never left them.

For some time previous to his coming to Hamilton, his firm had been considering Canada as a new field for their products, and in Sept., 1921, Mr. Norton came over to Hamilton to start the new factory.

Since that time he has been constantly improving conditions, production methods, and making friends. Mr. Norton is feeling particularly good these days for business is picking up, and he is also getting out a new catalogue which is going to be well worth while. We saw the advance proofs and can speak with authority.

TIME STUDY WATCH

No plant is immune from the disease of non-productive effort, wasted time and lost motion and the losses incident to them would equal enormous sums if reckoned and totaled in terms of dollars. A new decimal duration time study watch has recently been placed on the market which incorporates some interesting features. The graduated dial is so designed that it eliminates all need for calculations, the reading being direct from figures thereon. The dial contains a portion incompassing three minutes of observation, that indicates at any point of elapsed time exactly what the corresponding output per hour is. A small circle in the upper central portion contains a small hand which records the revolutions of the large hand up to and including thirty minutes. This time study watch is especially designed to facilitate the deduction of the time wasted and automatically reduces the net time to output per hour. The watch is manufactured by the Mortimer J. Silberberg Co. of Chicago, Ill.

REAMER DRIVES

"Reamer-Drives" operated by small electric motors placed near the assembling benches are doing away with the antiquated "strong arm" or manual methods of hand reaming. By expediting the reaming of finished holes where sizing is essential, they improve the quality of the work, reduce the handling charges, save time and tedious, slow, intermittent work of turning reamers by hand is eliminated. The reamed hole produced by a steady power drive is smoother and better finished, of greater accuracy and consequently longer life. Only 1/16 h. p. is consumed when the machine is used. The gearing of the head is so composed that this force is amply sufficient to handle reamers as large as 1½in. It is a sturdy, well built machine. All parts are thoroughly safe-guarded, readily accessible, enclosed to retain oil for lubrication and it is entirely self-contained. A pedestal of the vertical type carries the driving motor which is belted through a three speed cone to a self-locking worm gear reduction which rotates the chuck carrying the reamer. The operator stands directly in front of the reamer and holding the work free-hand (floating holder) feeds it on the slow turning reamer (which centralizes itself) with the fastest possible speed producing better results than with rigid fixtures. These machines are built and marketed by Geo. H. Blettner Co., 1841 W. Jackson Blvd., Chicago, Ill.

The elements that give brittleness to copper have little effect on the conductivity of the metal.

Ample space should be provided at the extreme ends of reciprocating parts of machines, such as planer tables, shaper rams, etc., so that there is plenty of room for a person to pass when machine is in motion.

News From the Welding Field

Overcoming Defects and Failures in Welding

Allowance Must be Made for Expansion and Contraction—Methods of Eliminating Distortion of Welded Parts—Causes and Remedies—Making Calculations in Advance

By M. PIETTE

THERE are many ways of taking care of expansion and contraction, but the four principal methods are as follows:

(1) Arrange the lines of welding and weld in such a manner that the effects of contraction are distributed and divided up so as to neutralize their effects.

(2) Distorting before welding the piece, in an opposite sense to that which contraction effect would produce.

(3) Producing, in certain cases, a sudden contraction of a portion of the piece by local cooling of a heated zone.

(4) Preheating the piece to be welded.

Sheet Welding

In welding two pieces of sheet metal together, suppose they are placed edge to edge as shown by dotted lines in Fig. 5 and a blowpipe is applied at A it will be found that the plates diverge as shown by full lines and form an angle. This is the result of the expansion of the zones Z which consist of sectors of radius R, for example.

The length 1. of each edge increases and the plates separate a certain amount at B.. When the weld has progressed a certain length two other phenomena come into play. The zones Z now commence to cool and tend to close the angle at B; the plates should therefore return edge to edge but the transverse contraction of the molten bath becomes prominent and these two phenomena lead to the overlapping of the plates at their extremity B. It is for this reason, therefore, necessary before commencing to weld to set the plates so that the edges are not parallel but set at a slight angle.

These contraction effects cannot be determined in advance for the reasons previously explained, but it is generally agreed that the separation or correct amount of divergence which should be given at B should be from 3 to 5 per cent. of the length of the weld.

In thin plates, say below ⅛ inch, tacks or short welds at intervals of about 2 inches are frequently made previous to welding. These should be made with a welding rod. In welding material about ¼ thick expanding the line of welding, previous to welding, by an amount that will practically equal the contraction effect, gives very good results and we shall examine a practical application of this method later.

Cylinder, Pipe and Tube Welding

The welding of pipes, tubes and sheet metal rolled into cylindrical form is extensively applied in the sheet metal industry, in many cases the applications to this class of work exceed those of ordinary plate welding. It is worth noting in passing that manufacturing sheet metal products by the welding process

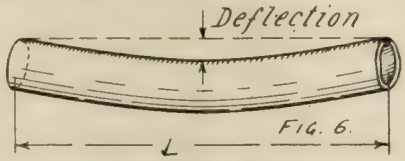

Fig. 6.—Longitudinal distortion.

produces far more satisfactory results than are possible by riveting or other means, as the finished product is not only stronger and more uniform, but the joints are air and fluid tight.

In welding cylinders, pipes and tubes the distortion produced during welding can be placed in two classes, viz.:—Longitudinal distortion and circumferential distortion. The longitudinal distortion, shown in Fig. 6, is due to the

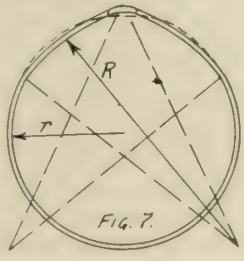

Fig. 7.—Circumferential distortion.

diminution in length of the line of welding. The circumferential distortion shown in Fig. 7, is due to the transverse contraction of the molten bath tending to straighten the plates in the vicinity of the weld.

This circumferential distortion becomes prominent when the material is thin, because the size of the molten bath is, in this case, comparatively greater than in the case of much thicker plates; the contraction effects are therefore greater and further the resistance of distortion in the neighborhood of the weld is relatively weaker. The circular section thus becomes oval, due to the pull of the contraction forces, and the radius of curvature is increased to R, as shown in the diagram. It is possible to overcome this oval distortion by making allowances in the preparation of the edges, in other words, by hammering the edges of the plates so that after welding the contraction stresses practically produce a circular shape. The phenomenon of oval distortion diminishes in proportion as the thickness of the pl: and the diameter of the cylinder increases because the molten bath is proportionately less and the contraction effects are distributed over a larger surface.

The longitudinal distortion, which is in the form of a deflection, is from th to four thousandths when the diameter of the cylinder or pipe does not exceed 100 to 150 times the thickness of the plate; above this value it diminishes. If the preparation for welding is unsatisfactory or unsuitable jigs are used, the amount of the deflection may vary considerably. This is illustrated by the preparation shown in Fig. 8, in which the ends of the cylinder are drilled and the two chamfered edges of the plate are held solidly in position by plates bolted to the ends of the cylinder. This method is defective and brings about continuous curving or deflection of the edges which is usually corrected by hammering, thus making the welding operation more troublesome and requiring more time. It is, therefore, not advisable to adopt this kind of preparation when welding sheet metal in cylindrical form because the resultant effect is to concentrate the total contraction stresses along the line of welding, as is shown by the increased deflection.

Welding of Tubes

In the welding the longitudinal seams of cylinders or tubes, in which the thickness of the material is relatively thin, the preparation generally consists in tacking the two edges. Tacks, or short welds, at intervals of from 2 to 6 inches according to the thickness of the sheet are made the entire length of the seam, to hold the edges in position. This tacking can be carried out in two ways

Conclusion of a paper prepared for Acetylene Journal by the author, who is engineer to the Chamber Syndicate de la Soudure Autogene. The material has been translated and added to by Capt. D. Richardson, R.A.F.

chine, otherwise the sheets must be drawn with a hammer.

In welding the longitudinal seams of cylinders in which the material is comparatively thick above 3/16 inch, for example, tacking is seldom resorted to, the usual method being to set the plates at an angle as previously explained for sheet welding. When the length of the

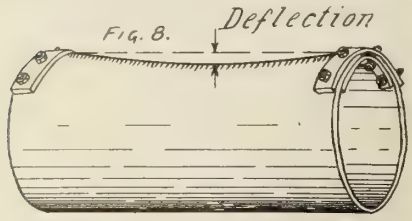

Fig. 8.—Deflection of tank.

weld exceeds 3 feet, it is advisable to start welding at the center of the seam either by commencing at a short distance from the ends of the plates and tacking at regular intervals the full length of the seam, or by commencing to tack at the middle of the seam and then tacking alternately on each side of the first tack.

The latter method, shown in Fig. 9, is the best and avoids loss of time. The

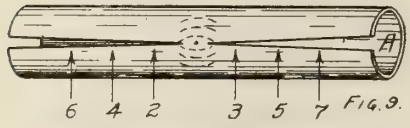

Fig. 9.—Allowing for contraction.

effect of tacking in the center is to make the plates take a V form, as shown. The effect of tacking at 2 is to cause the edges at 3 to approach each other, and thus make the tacking at 3 a simple matter. In the meanwhile the contraction effects at 2 draw the edges at 4 together, and so on, the expansion and contraction effects thus assisting the operation.

Tacking should be well done and preferably without using a welding wire,

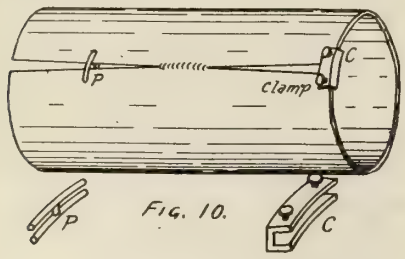

Fig. 10.—Providing for contraction of sheets

thus leaving the hand free to guide the plates. It is not sufficient to just melt the metal together at the tacked points, as the heat effects easily break one of more of the tacks. The effects of tacking thin sheets and the subsequent welding is to produce distortion or buckling of the welded sheet. A practical method of rapidly and effectively remedying this is to make use of a rolling machine, otherwise the sheets must be drawn with a hammer.

In wielding the longitudinal seams of cylinders in which the material is comparatively thick above 3/16 inch, for example tacking is seldom resorted to, the usual method being to set the plates at an angle as previously explained for sheet wielding. When the length of the weld exceeds 3 feet, it is advisable to start welding at the center of the same and weld in opposite directions toward the ends of the cylinder. By adopting this method, shown in Fig. 10, the amount of divergence is less than that necessary when welding from end to end and the longitudinal distortion or deflection is diminished. This is an application of the method of dividing the expansion and contraction effects.

On heating the center of the plates at the commencement of welding the edges separate and a suitable wedge, for preventing the plates getting out of line, can be inserted. The small device shown at P, Fig. 11, proves excellent for this purpose. It consists of two round rods or tubes 4 to 5 inches long welded to a vertical piece of iron rod, the length of which is made to suit the thickness of the plates. Displacement of the plates being welded in a vertical sense is entirely eliminated and the welder can move it along the seam as the weld advances. This device can be supplemented by the U clamp, shown at C, which is fixed at the extremity of the plates and may be used by itself when welding cylinders of short length. The screws simply keep the device in position and should not interfere with the free expansion and contraction of the plates.

GEOMETRIC CONTROL OF GEAR TEETH SHAPES

(Continued from Page 41)

the bevel gear, and of course, of equal pitch. Thus the pitch angle becomes the determining factor.

Odontograph Method

There are several variations of the generating principles of producing the tooth curve. The first, the Odontograph method, is not strictly within the classification, for the curve produced is only a compromise. In this method, which is most applicable to shaping machines, the point of the tool which describes the tooth curve, is constrained to move in an arc of a circle which approximates the curve of the involute tooth which is to be imitated. Remembering the way the true involute is described—by unwrapping a tangent from the base circle—it will be seen that it continually becomes of greater radius as it swings outward. Also the correction applied to the true full depth involute (as by Brown & Sharpe) to prevent interference consists in a narrowing of the tooth tip. Therefore if an arc of a circle be chosen for the Odontograph such that it is practically correct at the pitch line, it will be found that the tooth produced is increasingly scant all the way to the tip, and increasingly full inwards towards the root.

Generating Principle

This method is not nearly as much used as the true generating processes of which there are two, viz., the Describing Generating and the Moulding Generating. Both apply almost exclusively to the involute curve, or its variant the octoid in the case of moulding generating bevels. The describing generating process, which is a shaper process in application, is the less important of the two commercially but is theoretically correct, producing perfect involute teeth. In this process the shaper tool is made as previously described for templet planing, that is, with a curved end to form the fillet at the root of the tooth, but in this case it is ground to form also the part below the base line. The remainder of the tool is a straight shank and the point where this straight portion joins the formed end is the describing point of the tool, corresponding to the describing point of the unwrapped tangent. In addition by the reciprocating cutting motion of the tool along the tooth, means is provided to feed the tool sideways so that the describing point traverses a path tangent to the base circle of the gear, while the gear is synchronously rotated. This gives the exact motion of the tangent being wrapped up on the base circle and compels the describing point to travel a true involute curve till it reaches the base circle. The flank of the tooth below the base circle and fillet in the clearance have at the same time been formed by the end of the tool projecting beyond the describing point. This is for one side of the tooth only but the principle is the same for both. This finds application in a number of British and Continental gear planers.

USING THE CAMERA

(Continued from Page 45)

ginal, in other words the object stands out in bolder contrasts; as regards the tracing example there is no doubt of the superiority of the reproduction over the original. After the negative has been taken by the camera it is developed and prints made in the usual manner followed in photography.

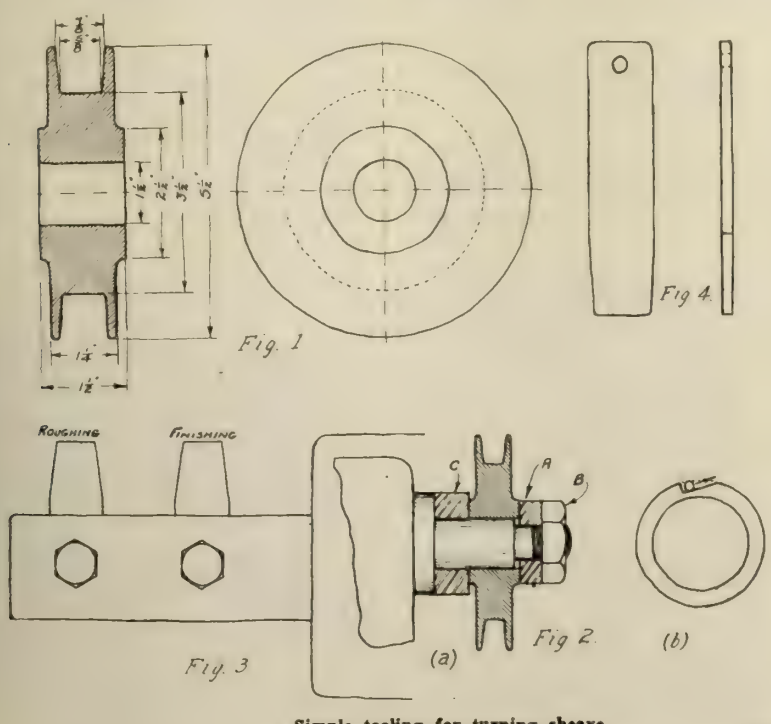
We use these photos by fixing them onto paste board and sending them into the shop similar to the using of blue prints and as they are all one size, are easily kept in boxes in the tool-crib to be called out on check as required. Further, a complete set of assemblies and details are pasted in a folder and kept in the superintendent's office so that he can readily refer to them when necessary without going through a cumbersome folder as is the practice in most shops. When another copy of any print is required the boy simply gets out the original negative and the supplying of the drawing or reproduction is a matter of only a few minutes, just making a print from this negative.

Practical Ideas From Practical Men

TOOLING FOR SIMPLE JOB

By H. Alton

Some of the simplest jobs that are taken care of in the machine shop often develop some interesting fixtures when it becomes necessary to take care of such work on a production basis. A good example of one of these jobs is that of turning the groove in a large number of small cast iron sheaves for use on overhead rail carriers in the new cold storage warehouse recently erected by the Harbour Commissioners of Montreal.



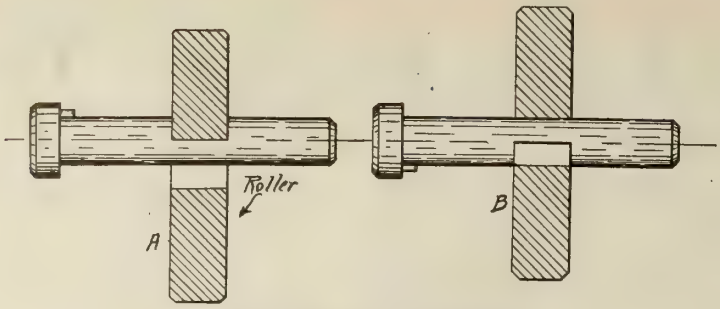
This sheave is shown in Fig. 1 and is approximately five and one half inches in diameter. The groove is one inch deep and is seven-eights and five-eights of an inch wide at the top and bottom respectively. The groove is not turned from the solid, there being a groove in the casting.

Previous to the turning of the groove, the sheaves are bored and the hubs faced on both sides. The turning operation is done on a Jones and Lamson flat turret lathe. An expanding mandrel of the single roller design is used as shown in Fig. 2. In this figure there is also shown the general method of gripping the sheave. The combination of clamping the sheave between two collars by means of the nut and at the same time using an expanding mandrel, is one that provides, to all intents and purposes, a drive that is well nigh positive. The construction of the expanding mandrel is very simple. One groove is machined in the mandrel as shown at b in Fig. 2. The mandrel is case hardened before being placed in service. In the groove is placed a piece of hardened drill rod that is retained in place when assembled by the collar C. When the roller is located in the deepest part of the groove, as shown in the illustration, the diameter of the mandrel over the roller is the same as it is, if calipered at the full diameter, namely 1½ in. The sheaves are a sliding fit on the mandrel. After the sheave is placed on the mandrel the collar A is slid on and then the nut put in place. This nut is brought up fairly snugly by means of a spanner wrench. If the friction between the sheave and the two collars is not enough to keep the sheave from moving on the mandrel when turning operations commence, the slightest movement of the sheave causes the roller to move in the direction of the arrow which in turn causes the mandrel to grip the sheave positively. The collar C is used to keep the roller in position when changing sheaves. However, it was noted that the operator had the mandrel marked and always stopped it with the roller on top.

After placing the sheave on the mandrel, turning is commenced. Two solid tools, one for roughing and one for finishing are mounted on a special bar, as shown in Fig. 3. The outer tool is used for roughing and the inner one for finishing. Both tools are slightly narrower than the finished width of the groove. The roughing tool is fed into the groove, and the scale on both sides and the bottom is removed. The turret is moved slightly, longitudinally, in order to widen the groove. Thus the groove is prepared for the finishing cut. No gauging as to diameter of the bottom of the groove, nor of the width of it, is made in the roughing operation. Because of the narrow tool both sides and the bottom are not being machined at the same time and possibly heavy cutting is avoided. Thus tendency to chatter or to dig in is also made practically impossible.

The finishing tool is fed into the groove in much the same manner as the rougher. The bottom of the groove is cleaned up and then the sides are machined. The gauge shown in Fig. 4 is used to check the width of the groove in the finishing operation. No direct reference to the diameter of the bottom of the groove is made at any stage of the operation. The wire edges of the top of the groove are removed with a file. On the design of turret lathe used in this operation the turret is equipped with only longitudinal feeds. The cross feeding is accomplished by means of travelling the head transversely. The removing of the sheave is also simple. The nut is started by the wrench. Then the operator reverses the spindle and grasps the nut in his hand. The collar A is then removed and a slight blow loosens the sheave on the mandrel. A production of from twenty to twenty-five sheaves per hour can be maintained.

Some of the methods employed in this operation may not appear to be along the lines of the best mechanical practices, but this fact cannot be disputed, and that is the sheaves practically all pass a final inspection and the cost is well within the estimates of the firm. Under present conditions, any method that produces the work so that better than ninety-five per cent. of it passes inspection, and at the same time is within the estimated cost, ought not to be too severely criticized.



Simple tooling for turning sheave.

WHY THE EXHAUST VALVE DID NOT WORK

By G. Blake

The writer, whilst working in a general repair shop some years ago, was one day sent out by the foreman to examine a gas engine in a bakery, the complaint was that is pulled up when the load was on. The engine was of a very old type, but it seemed to be in good working order as far as the writer could ascertain, the pulling up with the load on indicating that some part was not functioning properly. When the engine was running it was noted that the small cam roller, which actuated the exhaust valve mechanism, appeared to have a very small amount of lift, the engine was accordingly shut down and

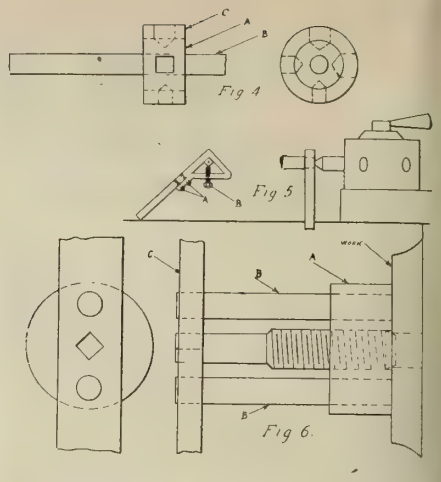
Why the exhaust valve did not work.

the roller examined and it was discovered that the pin on which the roller worked had become worn on the top side, that is the side on which the thrust took place when raising the valve to exhaust the exploded gases. This pin was worn practically half way through, see sketch A, consequently the valve did not open sufficiently to allow the gases to escape, which would account for the pulling up when the load was on. The old pin was turned half way round so as to present the unworn part to the bore of the roller, see sketch B, thus giving the valve nearly the proper amount of lift. This of course was only a temporary adjustment until a new pin could be made. The engine pulled all right on lead after this simple alteration.

THREE SIMPLE SCALE HOLDERS

By Harry Moore

Quite apart from the combination sets and other standard scale holders now on the market, there are many simple devices for holding a scale that any mechanic can make in a few moments. For example; nothing elaborate is required to hold a scale securely in a true vertical position, as will be seen by a glance at the first Fig. accompanying this article. In this case a piece of 1¼ inch cold rolled steel has been turned parallel and one end slightly concaved. To hold the scale a piece of common elastic B is used, the only requirement being that it shall be tight enough on the steel piece to hold the scale securely. If the scale is pushed through the elastic until the end rests squarely on the surface plate, a true vertical position is assured.



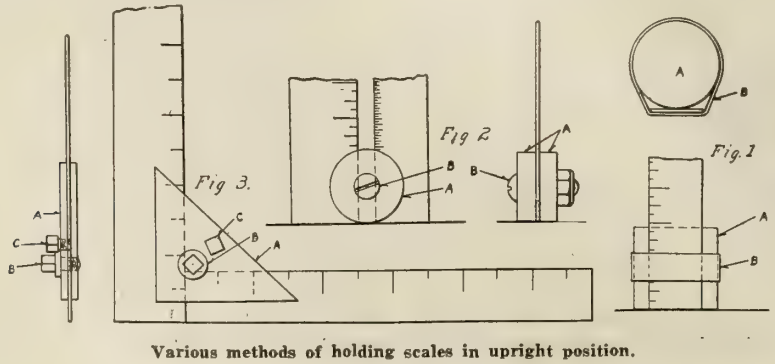
Very often two scales held in this position are handy in laying out work; one graduated in fractions, the other in decimal parts of an inch, or millimetres. The writer first came across this idea during the war when several jobs were being put through to the French measurement. To make assurance doubly sure some of the men fell into the habit of transferring all dimensions into inches, as 75 m.m. for instance, means absolutely nothing to a man unaccustomed to such, but a table of equivalents clears things up somewhat. As mentioned before, it was the custom to make sure before final marking, to try the surface gage on an ordinary scale. Two washers A about ¼ inch thick are used to hold the scales vertical, the hole in the center of one being slightly larger than the screw B to accommodate any little difference in the thickness of scales by allowing the washer to rock. The diameter of both washers is of course equal, the scales are tightened in place by the button head screw B and a nut on the back.

In the last figure two scales are held at right angles by two triangular pieces of ⅛ flat steel A, drilled and tapped for a collar head tightening screw B and a square head adjusting screw C. This simple device holds two scales together rigidly, and if the ends of the scales are in good condition they form a very good square; handy in many cases where an ordinary square could not be used.

MACHINE TAP WRENCHES

By Harry Moore

Several pieces like A can be made up to take different size taps, or if preferred the wrench can be made as shown in Fig. 4 which takes care of four different sizes of squares. The hole for B is drilled through the centers, and on the outside, equi-distant apart, are countersink holes, the top diameter of each being a little larger than



the distance across the corners of taps. Next a ring C is made, drilled the same with four equi-spaced holes and filed out to take the squares of taps. This ring is then either driven tight or shrunk into A as desired, the whole making a very neat wrench when finished.

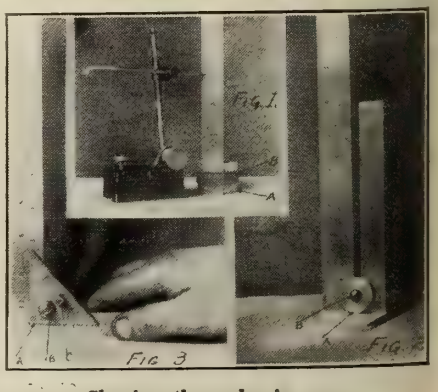


Fig. 4 shows a wrench which has proved useful in connection with a small turret lathe, rather badly worn. Many shops make use of these old timers and find them very handy for doing odd jobs. This is particularly true of tapping operations, for if a cutter of suitable size can be found the tap is soon taken care of by using a center in one of the turret holes and holding a monkey wrench on the square to keep it from turning. This is however rather dangerous, for the moment the tap gets through the nut, or whatever is being tapped, it is likely to jump away from the wrench—which of course has no actual grip on it—and drop into the chuck jaws. With the wrench shown the operator has control of the tap all the time, and when it is through the work it can be held safely back on the center until the machine is stopped. Made of rectangular stock it is best as shown to form a triangular holder, two screws A securing the ends together, and a cap screw B being used to tighten the taps in place; various sizes can be held.

In the last example, Fig. 6, a special guide and wrench are shown, designed for tapping a number of holes in a horizontal direction, this being necessary because they were drilled that way and

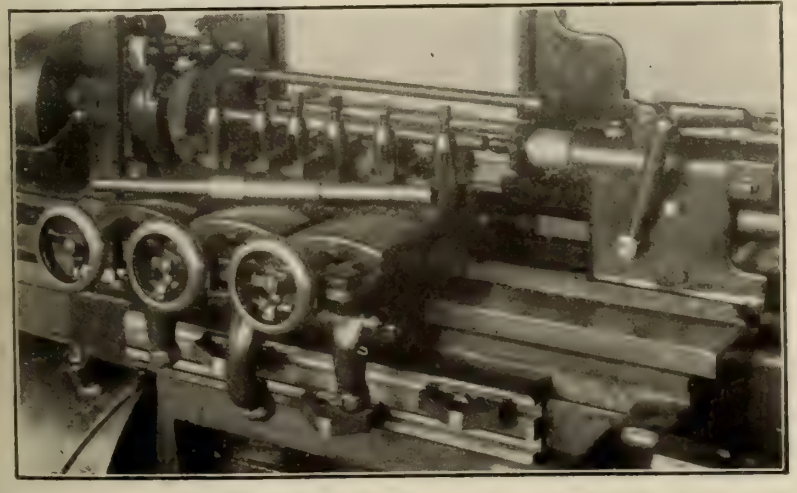
Showing the scales in use.

New Things in Shop Equipment

AUTOMOTIVE PARTS GRINDING MACHINE

There has recently been placed on the market a grinding machine particularly designed for operation on crankshaft bearings, valve seats, valve stems, piston rings, pins and push rods. The machine is made in two styles one for power feed and the other for hand feed. The power feed machine provides power traverses and automatic reverse for the table and an automatic in-feed for the grinding wheel. Two back rests with wooden shoes and two crankheads are furnished while adapters are provided for holding flanged end cranks. The machine is manufactured by the Cincinnati Grinder Co. of Cincinnati, Ohio.

NECKING ATTACHMENT FOR FULL AUTOMATIC LATHES



An attachment provided for the purpose of squaring shoulders or necking below the turned surfaces of work for grinding, or for any other operation where a cross feed can be utilized, has just been placed on the market. The attachment consists of multiple carriages to replace the regular carriage of the lathe. One, two or three (as shown) of these carriages may be adjustably clamped to the front way of the bed. They carry regular tool slides and provision is made for multiple tool posts. Adjustment for depth of cut is made by the handwheels shown mounted on screws with graduated dials reading in thousandths of an inch. The cross slides are actuated, through the medium of roll carrying arms, by the adjustable cams mounted on a cam carrier which is reciprocated longitudinally by the main feed cam of the machine. These cams can be adjusted to provide any sequence of the cross movements or all slides may be moved in unison depending on the nature of the work. Suitable oil distribution is provided and all of the automatic functions of the lathe are retained. This attachment may be readily removed and the regular carriage with its actuating parts applied. The device is being manufactured and placed on the market by the Pratt and Whitney Co.

COMBINATION BENCH MACHINE

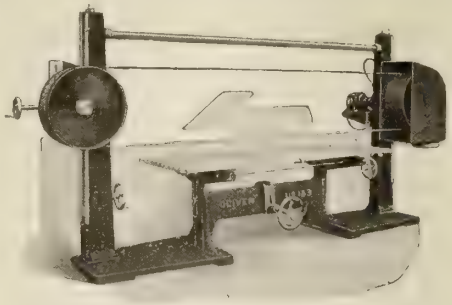
A rather unusual bench machine has recently been placed on the market. This machine is a combination tool intended for use in the garage or service station. By employing various attachments that are supplied, the machine can be used for drilling in wood or metal, for surfacing or sanding, disc grinding, polishing, buffing, rough or tool grinding, or for rip-sawing wood. The table through which the rip-saw protrudes can be removed in order to allow the various attachments to be adjusted, or the table can be tilted, for sawing at an angle. A horizontal disc placed at the upper end of the vertical spindle, is intended to be used for disc grinding or surfacing. The frame of the machine is cast iron and the two spindles of high grade carbon steel. Both spindles run in bronze bearings. The vertical spindle has a range of movements of 3½ in. without adjustments, and is supplied with a Jacobs chuck which will take drills up to ⅝ in. in dia. The drilling table is adjustable when in position. This machine is manufactured by the Ster-O-Lock Mfg. Co., of Chicago, Ill.

14-INCH TOOL-ROOM LATHE

There has recently beeen placed on the market a motor driven tool-room lathe that embodies some noteworthy features. The motor is mounted on a shelf beneath the oil pan where it cannot obstruct light or interfere with the operator. The drive is through a feed box and an Oldham coupling having no screws or bolts and the motor may therefore be removed or replaced without any other preliminaries than withdrawing the holding down bolt and disconnecting the wires. The motor pinion, being supported by independent bearings remains in place in mesh with the second gear An oil-tight change-gear box is mounted so as to swing about the centre of the second shaft, and from a pulley on the exterior of this box a belt goes directly to the single drive pulley on the spindle. The weight of the gear box maintains a constant tension on the belt, thus eliminating trouble from the stretching of the belt and dangers of breaking from possible snagging of the tool in the cut. Nine changes of feed are available by means of a gear box, and are controlled by the position of the two levers on the front of the pedestal. A positive interlock prevents interference of the gears. The usual form of back gearing, mounted on a quill running on a stationary eccentric shaft, is provided. The ratio of the back gearing is such that nine additional speeds are available, making 18 in all. A complete range of threads and feeds is provided by the two gear boxes controlled by the two upper levers. Improvement in the design of the carriage and cross-slide add rigidity and convenience. The ratio between the cross-feed and carriage traverse is carefully calculated and intended to give accurate tapers when the two are used together. An extremely wide range of tapers is available through the taper attachment. The tail spindle is graduated and the foot stop is provided with an improved form of locking device. Every moving part except the spindle nose and the lead screw is completely covered. The motor is stopped by means of conveniently located push buttons. The speed-change levers are interlocked with the electric control mechanism, so that the first movement in the act of changing the gear speeds, operates to slow down or stop the motor without the attention of the operator. The treadle extending along the front of the base is connected with the swinging gear box so that the operator can, by pressure of his foot, stop the lathe for the purpose of calipering or inspecting the work without stopping the motor. The pressing the treadle raises the gear box and releases the tension of the belt, the operator is thus enabled to stop the lathe from the extreme end without the necessity of reaching the control button. In its lower position the weight of the gear box rests partly on the belt and partly on an adjusting screw, so that the belt tension may be adjusted as the nature of the work may require. This lathe is manufactured by the Hendey Machine Company, of Torrington, Conn.

Necking attachment for full automatic lathes.

STAYBOLT MACHINES



A staybot machine that has some really novel features has recently been placed on the market. The machine is used for turning simultaneously the taper and straight diameters on radial, button-head and crown staybolt forgings, and for threading both the straight and taper ends, also simultaneously, in uniform pitch and continuous lead. After the turning operation, the cutters in both heads are replaced by chasers. To enable the machine to be adjusted to any desired length within its range, the rear die-head carrier is adjustable on the slide by means of a fine-pitch screw. A permanent spacer bar, very accurately made, is furnished with each machine. This bar has twenty-three holes accurately bored and spaced one inch apart, to correspond with the various lengths of the bolts. The rear die-head carrier has a pin, which when inserted through any of the holes in the bar sets the die-heads in continuous lead without further adjustment. A cross-slide with hand cross-feed and hand longitudinal adjustment is provided for facing and undercutting the button-head bolts. The machine has a capacity for bolts from ¾in. to 1½in. in diameter and from 14 to 36in. long. The machine is supplied with a step cone or all geared head, the latter arranged for single pulley or motor drive. Seven hundred bolts 28in. long have been completed in one day of nine hours, by one operator. The machines are equipped with many of the common and well-tried devices and it is stated that these, along with the special features, put them in the class of big producers. The manufacturers are the Millholland Machine Co., of Indianapolis, Ind. They are marketed under the trade name of "Lassiter-Millholland" by the Dale Machinery Co., Inc., of New York City.

HAND PLANER AND JOINTER

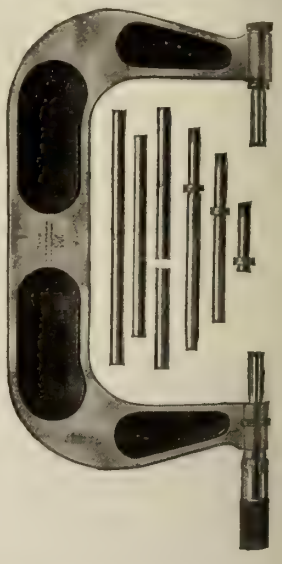
A portable, motor-driven planer and jointer has recently been offered to the trade. The machine is intended for mounting on a bench and is made in 4 and 6 in. sizes. The larger size planes widths of 6¼ in. while the smaller size takes care of widths of 4¼ in. Both sizes rabbett up to one-half inch. All parts of the machine are carried on the one base which is a one-piece casting so that the entire unit can be easily moved from one location to another. Hand wheels and screws are provided for raising and lowering of the tables. Provision is made for quick adjustment of the fence to any desired position on the table. When not required it can be moved out of the way. An aluminum safety-guard is provided for covering the knives, yet these do not interfere with the operation of the machine. Three tungsten-chromium steel knives are fitted to the cutter head. The head runs on self-aligning, closed-in ball-bearings, and is driven by means of an electric motor directly connected by means of a universal flexible coupling. The cutter operates at a speed of 3,600 r.p.m. on either alternating or direct current of 110 or 220 volts. A special attachment for sharpening the knives may be furnished when desired. The larger machine occupies a bench space of 32 by 18 in. These machines are manufactured by the Oliver Machinery Company, Grand Rapids, Mich.

SELF CONTAINED BELT SANDER

A machine intended for rapid sanding and polishing of cabinet work and large patterns, and also metal surfaces, has been placed on the market recently. The machine has an exceptionally wide range, and it will take care of work 42 in. high on table and 66 in. with table

Self-contained belt sander.

removed. Table has a travel horizontally of 36 in. and a vertical adjustment of 14 in. Belts are 10 in. and about 31 ft. long. The three principal parts of the machine are the power stand, idler stand and the table. The table is 96 by 32 in. and rolls on ball bearings. It is fastened to the base plates of the stands as shown, all the members being carefully machined and mounted in alignment. The two stands are connected with a rigid top stay, as shown.



For motor drive a slow speed motor is direct connected to the driving pulley, but high speed motors may be geared to the pulley also, the latter arrangement being shown in the illustration. The pulleys are 24 by 10 in., the large diameter being to assure long life to the belts, sand breaking off less than when traveling around small pulleys. The pulleys are rubber faced and run 600 r.p.m. A reversible switch permits running the bolt in either direction. The machine is made by the Oliver Machinery Co., Grand Rapids, Mich.

NEW LINE OF SMALL LATHES

A line of screw cutting engines ranging in size from 9 to 13 in. swing with the usual lengths of bed have been recently placed on the market. The machines are sold under the trade name of "Handy." They are general purpose machines designed especially for the radio industry, and for started and magneto service stations. The machines may be arranged for either motor or belt drive. The bed is of heavy ribbed construction and can be equipped with either bench or floor legs. The headstock has back gears and a large hollow spindle adapted to draw-in collet chucks. Provided with the machine are power longitudinal and cross feeds, graduated cross feed screw, and a set-over tail-stock. A plain or compound rest and a double friction countershaft having a cone belt shifter and self oiling bearings can be supplied. With this line of lathes the manufacturers are also marketing a plain turning lathe having a 10⅛ in. swing and a three foot bed, taking 12in. between centres. The machine is equipped with a plain rest, feeds from 0.002 to 0.040in. per revolution of the spindle, set-over tail-stock, three step cone, and self-oiling spindle. The countershaft is of tight and loose pulley type with roller bearings in the loose pulley. This machine is intended for plain turning where screw cutting is not necessary, and it is especially adapted for use in making small parts for electrical apparatus. The manufacturers of both these lines of machines are the Seneca Falls Manufacturing Co., Inc., of Seneca Falls, N. Y.

WIDE RANGE MICROMETER CALIPER

A very useful micrometer caliper of unusually wide range has recently been placed on the market. By means of the four detachable anvils, the tool can be adapted to measure from two to six inches instead of from three to six which was the range of the original design. The anvils can be quickly changed and are held securely in place by a knurled nut. One anvil is for measurement from two to three inches, another from three to four inches and so on throughout the range. The tool is especially adapted for use in garages and service stations where small pistons, many under three inches in diameter, and also large pistons for trucks and tractors require accurate measurements.

Wide range micrometer caliper.

It can measure all ordinary sizes of pistons and cover the same range of work as three or four ordinary micrometers. The micrometer is being manufactured by the Brown & Sharpe Mfg. Co. and in general construction it is similar to other micrometers of this make.

The Outlook is Brighter

THE AGRICULTURAL field in Canada has shown slow but gradual improvement during the spring season. Rural buying is on the upgrade, and while there is still considerable room for improvement, the results so far have been encouraging. Ontario and Eastern Canada are the localities which show to best advantage at present, especially for agricultural implements, while the West is as yet an unknown quantity. Until the outcome of the next harvest is definitely known, we can hardly look for much improvement in that section.

Given a good harvest, there is no doubt but that Western optimism would again prevail. There is a wonderful market for not only agricultural supplies in that part of Canada, but for other lines as well, such as hardware, dry goods, etc., so that the possibility of increased activity in the West, once the harvest is over, must not be overlooked. Now is the time to create good will, so that later, when orders are being placed, the manufacturer who remembered his prospects, even in dull times, will not be forgotten.

Lower Freight Rates Necessary

ON JULY 1, railroad freight rates in the United States will be reduced approximately 10 per cent. Practically all classes and commodities of traffic are affected by this decision.

The move has not been made any too soon. The reduction should have taken place long ago, and Canadian roads should immediately follow suit. There is considerable talk about lower rates in Canada, but little action. In the meantime manufacturers wait and grumble.

Under present conditions machines can be shipped from England by boat to Vancouver, then by rail to the Trail mines, B.C., cheaper than by boat to St. John, N.B., and from there dircet by rail to the mines. To get the significance of this statement look up the map.

The same machines can be shipped from England by boat and rail route to the Trail mines at approximately the same figure at which American firms in Denver, Colorado, can forward their equipment by rail.

A certain brand of spring wire can be purchased by a moderate user in Canada in completed condition cheaper than he can bring in the raw material from the States. Further examples of the hindering influence of high railroad freight rates are unnecessary, for we all realize the necessity of a revision downward.

The decision of the United States labor board to reduce the wages of railroad employees is also a move in the right direction. There may be some trouble about enforcing the reduction, but a firm stand must be taken. Since 1898 operating costs on the railroad have increased tremendously. Passenger engineers who used to receive $3.29 per ten hour day in 1898, now receive $6.08 for an eight hour day. This is an increase of 131 per cent. General wages have increased all the way from 131 to 414.3 per cent. for this period.

A reduction in freight rates here would allow Canadian manufacturers to reduce their prices on goods both for domestic and foreign consumption, and would stimulate production and increase buying in many ways.

Are All Inventors Lucky?

ARE ALL OUR present day inventions the result of painstaking study on the part of the inventors, or is accident, rather than necessity, the mother of many inventions?

According to some authorities, accident forms the chief pivot point in new discoveries, and to try and prove their theory they offer some interesting stories.

Careless workmen in a paper mill some years ago omitted to add any size to the pulp. The paper was thrown aside as waste, but some one accidentally used a scrap of this waste, discovered its absorbent character, and thus blotting paper was invented.

A glass cutter at Nuremberg accidentally let some aquafortis drop on his spectacles, and discovered a means of etching glass.

It was not from any set purpose of forwarding his own scientific experiments that Montgolfier one day undertook the responsibility of airing his wife's gowns, when she was called to leave the house. He observed, while engaged in this task, that the gowns became inflated and tended to rise when filled with heated air; and Madame Montgolfier, on her return, found her husband sending up little paper balloons, thus originating his famous invention.

Some years ago, an Ohio business man had a shop in a good situation, and many customers, but somehow his business was not profitable. There was evidently something lacking in his methods, and he worried so much on the subject that he found it necessary to take a rest. While on his way to Europe, he was standing one day in the ship's engine-room, when his attention was attracted by the automatic indicator of the propeller shaft's revolutions. The question suddenly occurred to him: "Why not devise a machine for recording sales in a shop." Hence the invention of the cash register.

At the hearing of a Dunlop appeal case in the House of Lords in December, 1920, it was mentioned that the idea of a pneumatic tire was suggested by the tying of a piece of water-piping around the wheel of a wheelbarrow.

At least one valuable invention was the offspring of sheer laziness. In 1846 a railway pointsman, who had to attend to two station signals some distance apart, decided to save himself the trouble of walking to and fro between them by fastening the two levers together with a long piece of wire. A broken iron chair served as a counterweight. The wire ran on into his hut, where he sat nightly by his fireside and worked the two signals without setting foot outside. Presently the railroad officials found it out, reprimanded the lazy man for his indolence, promoted and rewarded him for his ingenuity, and adopted the invention.

After these stories what decision can we arrive at? To our mind, although accident may have had a great deal to do with the inventions mentioned, there was more than pure luck connected with the development of the ideas. Vision was necessary, the power to follow out a lucky coincidence, and the will to carry on in spite of disappointments. The stories told barely scratch the surface, for underneath these so called lucky incidents we find the inventive mind and the will to persevere.

Several Advances In Quotations Have Occurred

Products Advance Slightly, Also Iron and Steel Bars In Some Localities—Wipers Drop In Price—Small Tool Market Fairly Active—Non-Ferrous Metals and Scrap Are Quiet

SHEET DELIVERIES ARE MUCH SLOWER

A FEW PRICE reductions and advances have occurred on Canadian markets during the week. None of these however are of great importance, simply reflecting the strength or weakness of the section in which the change occurs.

Iron and steel bars have advanced to $2.90 in the Montreal field, but $2.75 still holds good around Toronto. Competition is too keen in the latter mentioned locality to permit an advance, although it may occur any time now that Montreal has taken the initiative.

Copper products also advanced in price, copper bars being now $28; brass sheets, $22; copper tubing, $29; and brass tubing $25. These new prices became effective May 29.

Fuel oil went up four tenths of a cent, the net price per barrel being $10.80 in place of $10.40.

Wool packing has dropped in price, the amount varying between 4 to 6 cents per pound.

Machine tools are the same as last week, but small tools and supplies have improved slightly. The iron and steel market is firm, and May will show up as the best month this year.

Pig iron demand is lighter, but the market is firm. Non-ferrous metals and scrap are both quiet, but there has been no change in price, except in Montreal locality, where the revision is upward. These advanced figures mean little or nothing as the volume of business moving is not worth commenting upon.

The bolt and nut factories are busy and expect to continue active for some time to come.

The steel market in the United States has lost no strength so far as prices are concerned, but the demand is lighter. Producers are well sold up, and have orders on hand for at least two months. In fact several mills have not opened their order books for third quarter business. The coal strike is responsible for this cautious move, for should the strike continue longer than the next two or three months, the mills might not be able to produce.

The general freight reduction taking effect July 1, will reduce the average cost of making steel about $1.25 to $1.50 a ton. This will of course help the consumer.

Steel ingot production is running at about 38,000,000 gross tons a year, this being 3,000,000 advance over the figure for April. The present rate is practically double actual production in 1921.

Bars, shapes and plates are now quotable 1.69c minimum, while some early delivery business is being closed at premium prices. Nails range between $2.40 and $2.50. Tubular goods are very firm, the shading that was so pronounced two months ago having disappeared.

Connellsville coal has declined to between $3.00 and $3.25. Hoover's determination to bring about reasonable prices for non-union coal is largely responsible for the reduction. Small lots of Bessemer pig iron have been sold at $25, valley. Basic and foundry are quoted at $25 and $24 respectively. The market, however, is stagnant.

Toronto

June 1.

A FEW price changes have occurred during the week but nothing of outstanding importance. Wool packing has dropped slightly, while some copper products have advanced. The iron and steel market is firm, and it is quite possible that Toronto will soon advance their price on iron and steel bars to the same level as Montreal. In fact they would have done so before had competition not been so keen.

Iron and Steel.—Every week sees a little added strength in these two lines. The demand is general and covers a large field. Sheets are decidedly active, and deliveries from the mills are getting longer all the time. Four to six weeks from date of order is the best you can get, and in the majority of cases August delivery is now being quoted by Canadian mills. This does not infer however that the mills are working right up to capacity, for they are not. The reason is this:—They are operating at what they consider a safe margin, keeping in mind the possibility of a coal shortage. In fact some American sheet mills are not accepting orders from local jobbers because of present booking, and uncertain coal supply.

The past month has shown up to good advantage on the merchants' books, and an increase of at least 15 per cent. is expected when the figures of May have been totalled up. Building keeps very active, this also being responsible for added business in iron and steel lines. Following are local quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Non-Ferrous Metals.—There has been very little change in this section. A slightly stiffer tone exists, but the volume of trade moving has not increased to any extent. As a detailed account of the non-ferrous market appears on another page of this issue, we will simply print quotations to guide readers in their purchases:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals.—This is another quiet market. Compared with two months ago, it has improved, but placed alongside last week's report, conditions are identical. Following are prices quoted:

Copper, light, per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools.—This section is merely holding its own. Enquiries are better and are more direct in character, but outside of this, there is nothing new to report. What sales have been closed are for small amounts.

Small Tools and Supplies.—The demand for supplies has held up very nicely during May. Compared with April it will be about one third better, but to use this comparison is hardly fair, because April was a poorer month for some dealers than March. Looking on March figures, then totalling May sales, an improvement of between five to ten per cent. can be noted, the amount varying according to the dealer and his particular field. Some merchants feel that the new tax on the automobile industry will be sure to affect them indirectly, for a large percentage of the business closed recently has been for automotive factories.

Pig Iron.—Although the demand for pig iron is not exceptionally heavy, the market is firm. The mills are not running anywhere near full capacity, placing safe on a possible coal shortage, but a fair amount of orders are still being placed. The price is strong, being still $29.15. So far, Toronto has not felt the influx of British pig iron, but a few large users are completing enquiries.

Steel Pipe.—This market has a decidedly firm tone and the mills are quoting extended deliveries. Large users have already placed their orders so they are well protected. The small consumer simply has to take his turn, the mills doing the dictating.

Oils.—The demand for all sorts of oil continues to be fairly good. Fuel oil is up four tenths of a cent, the new price per barrel being $10.80. This is a very small increase, but shows the tendency. Following are present quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	0 88
Black oil, per gal.	0 17½
Cylinder oil, Capital	0 61½
Petroleum fuel oil, bbls. net	10 80
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00
Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bls. gal.	1 35
Linseed oil, raw, single bbls.	1 15

Waste and Wool Packing.—Several reductions in wool packing have taken place, and the new list shown below gives existing quotations. The previous prices were 30, 25, and 20 respectively.

WOOL PACKING

Arrow	24		
Axle	20	Anvil	16

Other lines of waste have not changed, but the demand has increased. The added activity in several branches of industry is reflected in these lines, the printing trade ordering a large percentage of the washed wiper business. Following are quotations:

WASTE

XXX Extra	16	Atlas	13
Peerless	11	X Empire	13
XX Grand	15	Ideal	18
Superior	20	X Press	11½
X L C R	14		

Colored

Lion	12	Fancy	13½
Standard	10½	Popular	9
No. 1	13	Keen	7½

Wool Packing

Arrow	30	Anvil	20
Axle	25		

Washed Wipers

Select White	13	Dark colored	13
Mixed colored	14		

Copper Products.—Several lines have advanced slightly, copper bars being $28.00 against $27.00, and copper tubing 29c. against 27c. Other new prices are, brass sheets, 22c, and brass tubing 25c. All these changes became effective May 29. Following is complete quotation list, showing new figures:

COPPER PRODUCTS

Copper Bars, ½ to 2 in.	$28 00
Cooper wire, list plus 10	
Plain sheets, 14 oz., 14x60 in.	28 00
Copper sheet, 14x60, 14 oz.	35 00
Copper sheet, planished, 16 oz., base	40 00
Braziers', in sheets, 6x4 base	28 00
Copper tubing, seamless	29
Brass Sheets	22 00
Brass Tubing	25

Montreal

June 1.

THE FEATURE of the local metal market is the stiffening of quotations in many lines. The strength in base price of steel at Pittsburg is reflected locally, and the new import tax is responsible for firmness in some quarters. Machine tools are quiet, and supplies are moving fairly well. Pig iron is quiet but the price is firm. Nonferrous metals are stiffer and business is improving The scrap market is dull.

Iron and Steel.—Jobbers and consumers allowed their stocks to get low during the very dull period of fall and winter, and being also influenced by the falling market, they kept out of actual purchasing, except for small lots intended for immediate use. In March when the bottom prices were reached, and the upward revision of prices was announced, it resulted in considerable business being placed with mills in the U. S. For some time past these mills have been receiving an increasing volume of business. Pittsburg base prices have risen from $1.30 to the present quotation of $1.60 in the past two months. In fact quite a tonnage has been recently placed in Pittsburg for early delivery at $1.75 base. Local mills are feeling this increase in business, and improvement is shown in many lines.

Jobbers increased their quotations during the week from $2.75 to $2.90 base. The mills are quoting jobbers in car load lots at $2.50 base, and on larger lots, representing the most attractive business, a price of $2.30 is named. Speaking generally, local jobbers state that the sales of iron and steel have improved with each succeeding month since the New Year, with the exception of April, which showed no improvement over March. Figures for May indicate that sales for the month will be about twenty per cent. ahead of April.

Building operations are still calling for a large volume of nails, spikes, reinforcing bars, and heavy hardware as well as some tonnage in structural sections. Merchant bars are moving fairly well, but rail orders are not yet in evidence. Sheets are active. Galvanized sheets in standard sizes and gauges cannot be obtained from British mills in quantities required to take care of the immediate demand. Blue annealed and black sheets are also moving well. Small steel lines are in fair demand but the business is somewhat spotty. Boiler tube quotations are very firm. Other lines are moving satisfactorily. For some time past a small weekly improvement has been consistently shown. Jobbers quote the following prices:

Iron bars	2 90
Steel bars	2 90
Reinforcing bars	2 90
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Since the last two-dollar a ton increase in price brought many firms into the local market, sales have been dropping off until conditions are again very quiet. In normal pre-war times, the Province of Quebec and the Maritimes, used about ten thousand tons of pig per month, but sales for the past year have been at about the rate of one thousand tons per month. Recent purchases following the jump in price were far in excess of consumption, hence the present dullness. Some sales of British Summerlee iron are still being made, and this is quoted at about one dollar per ton lower than Canadian iron. This condition is a serious one locally for Canadian mills and will exist as long as consumption in Britain is below normal. However, consumption in this vicinity is gradually increasing. No. 1 Canadian iron is quoted at $31.80.

Machine Tools and Supplies.—Little change in the machine tool situation is shown this week. The new import and sales taxes will increase prices of both wood and iron working tools. At present these figures have not been announced. Wood-working equipment is moving a little better than iron working tools, but the market is extremely quiet.

The supply business is fairly satisfactory as most of the jobbing shops are reasonably busy and are coming into the market more freely.

Non-Ferrous Metals.—An originally firm foreign market and the new import tax have caused the upward revision in nearly all non-ferrous metal quotations. Business is somewhat better than last week, although the demand is scattered and for small lots, the total volume is satisfactory, and an improvement over the figures for any single week for some time past. Local jobbers quote the following prices:

Lake Copper	17 25
Electric Copper	17 00
Castings, Copper	16 75
Tin	35 00
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metals.—The scrap market is very quiet. Prices are somewhat firm owing to an increasing number of inquiries, but the holdings are small in this locality. The following prices are quoted by dealers:

Copper, light per 100 lbs.	9 50
Copper, crucible	12 50
Copper, heavy	12 50
Copper wire	12 50
No. 1 composition	9 50
New brass cuttings	7 00
Red brass turnings	8 50
Yellow brass turnings	6 00
Light brass	4 00
Medium brass	5 00
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	12 50
Boiler plate, per gross ton	8 50
Heavy melting steel	10 00
Axles (wrought iron)	9 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	22 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	18 00
Cast boring	3 00

Pittsburg

June 1.

THE STEEL market has grown still quieter in actual turnover, but has lost no strength, as producers are well sold up and are assured of as full oper-

ation as physical conditions will permit for a couple of months or longer.

Whether buyers would continue to purchase now, for later deliveries, if they had the opportunity, is an open question. The opportunity is lacking in most cases, for some mills have not opened their order books for third quarter business, having been deterred from doing so by uncertainties as to ability to produce if the coal strike continues beyond the next couple of months. They are also doubtful whether all the buying tendency at present rests upon the solid foundation of requirements. In other words, the mills are afraid of there being speculative buying, for consumers are now as anxious to buy as they were a few months ago to refrain from purchasing.

Of course some of the tonnage now on books will not be shipped until after July 1, through some mills being behind in deliveries, while several sales have beeen made for July delivery. Little regular third quarter business, however, has been entered. The American Sheet & Tin Plate Co. will in all probability have opened its books for third quarter sheets and tin plate before this report reaches the readers. In bars, shapes and plates there may be no formal book opening at all, on account of so much of the tonnage now entered lapping over into the new quarter.

Steel ingot production is now running at about 38,000,000 gross tons a year, against 35,000,000 tons April 1, and 20,000,000 tons last December. The present rate is practically double the actual production in 1921, and falls only a few per cent. short of the production in 1920, when there was a strenuous demand for the major part of the year.

An interesting thing about the steel position, is that there is a very strong market when production is at the rate of 38,000,000 tons of ingots a year, for this is only between 70 and 75 per cent. of capacity, which probably lies about half way between 50,000,000 and 55,000,000 tons. Before the war it was commonly held that a strong steel market, with prices stiffening, could not develop after a depression until production reached 85 or 90 per cent. at least. The difference between recent and pre-war conditions is that before the war the steel industry was always able to operate at capacity when it had the orders, while since 1916 which was a year of capacity production, there has been no time when there was a full demand that capacity operation was possible.

In 1917 and 1918 there was practically continuous shortage of coke, due to transportation difficulties, together with some shortage of labor. Late in 1919 there were in succession the iron and steel strike and the bituminous coal strike, and when the industry had gotten over these there came the outlaw railroad strike April 1, 1920. Now there is the bituminous coal strike.

Perhaps in a pinch the steel mills could produce considerably more than they are making, but evidently the buyers of steel do not think they could. They are acting as if there is a possibility of a shortage of steel, and there is practically no doubt that actual consumption at present is less than production and shipments. Consumption no doubt is increasing and may catch up, but to keep the steel market strong continuously in the future there must be considerably greater consumpt on or a continuous inability of the steel industry to function up to capacity. There must for instance, be a breakdown of the railroads after the coal strike has ceased limiting steel production, or some other trouble.

Bars, shapes and plates are now quotable at 1.60c as minimum, and it appears that there is some buying, for early deliveries, at premiums, probably involving no large tonnage. Nails continue to be quoted at $2.40 by the American Steel and Wire Co. and at $2.50 by the independents, but as the leading interest did not follow the advance made by the independents about the middle of April, it has been increasingly difficult for the independents to sell much tonnage at their higher price.

Hoops, bands and hot rolled strips are all quoted at 2.25c, chiefly, perhaps, because mills still have a considerable tonnage of old business on books, at less than 2.00c. Tubular goods are very firm at regular prices, the shading that was so pronounced a couple of months ago having disappeared.

There are no new developments in the union bituminous coal strike, which has now lasted two months, and may last two or three months longer. The various non-union strikes have held out very well thus far, but are hardly likely to last as long as the regular union strike. In the Connellsville region, which is of particular interest to the iron and steel industry, there have been reports for several weeks of men drifting back to work, and this drift is now causing a slight increase in production. The guess among operators is that within a few weeks there will be a stampede back to work.

Connellsville coal has declined in the past week as rapidly as it advanced in the previous week, and is now quotable at $3.00 to $3.25. The cause of the decline was withdrawal from the market of many buyers, who were influenced by Secretary of Commerce Hoover's determination to bring about reasonable prices, for non-union coal, on the other hand, has advanced sharply, chiefly on account of buying by one steel interest, which is about to put a blast furnace in operation. The market is now all of $7.00 for either furnace or foundry coke. The advance shows how limited the offerings previously were.

Several small lots of Bessemer pig iron have been sold at $25, valley, which is now the quotable market against the nominal figure of $26 given a week ago. Basic and foundry are quotable at $25 and $24 respectively. The market is quite stagnant.

The general freight rate reduction ordered by the Interstate Commerce Commission amounts to 10 per cent. in Eastern territory, i. e., rates after July 1 are to be only 26 per cent. above rates in force just before the general advance of August 26, 1920, instead of 40 per cent. above. Thus, in general, 35 per cent. of that advance is taken off. This, however, does not put the iron and steel industry back 35 per cent. of the amount by which its freight charges have increased since 1913, since there were various advances before that of August, 1920, and in particular there were some stiff advances in coal, coke and iron ore rates when there were not corresponding advances in the class rates. A rough guess would be that the present reduction will reduce the average cost of making steel $1.25 or $1.50 a ton.

Non-Ferrous Market Shows No Change

SPEAKING on conditions in the Canadian non-ferrous market, Ernest W. Knight, Frankel Bros., Toronto, says that there has been no material change in the copper situation. "The market has been a little erratic but no marked alteration in the quoted price has materialized," continues Mr. Knight "and at the commencement of the month of April, the New York market showed some signs of life, based on the fact that the English market suddenly grew stronger, whilst exchange rates remained in last month's position. With the decline in exchange, which has now taken place, the English market has dropped pro rata and English values are, therefore now on a par with American values. No. 1 Lake is quoted at 12 7-8, Electrolytic at 12 3-4 and casting at 12.50 and there is no scarcity of red metal at these figures.

"When the Genoa Conference first went in session, the producers withdrew a considerable amount of metal from the open market, but this has now been replaced, and the high hopes which were entertained at the outset of the conference have apparently given place to a feeling of resignation. No rise is anticipated, but on the other hand, there is little likelihood of any decline. Consumers, therefore, cannot be far wrong in buying futures at current values.

Caution Necessary

"Tin is again fluctuating in an erratic manner and purchasers are just as likely to be right by buying on any one particular day as on any other. Tin, at the present quotation of 31c., appears to be cheap, but this is largely owing to the fact that the present value is much below that to which we have become accustomed during the past few years. It is not so very many years ago since tin was purchased freely at from 12-5-8 to 13c. per pound, and when one considers that this price ruled for a period of about 5 years, from 1894 to 1898, inclusive, it is pretty hard to decide exactly what is likely

to happen in the immediate future. There is not however, likely to be any marked reduction in price but the advance in sterling exchange should make a difference of 1c. to 2c. Caution should, therefore, be exercised in the purchase of this commodity for futures.

"The market for aluminum continues about the same. Ingot metal is quiet but sheet and wire are in fairly good demand. Prices remain at much the same level as last month but with a strong upward tendency, with the outside market quoting for 98-99, 17¼ to 17¾, 99, and over at 18.50. The Trust, however, are quoting for 99 p.c., 20c. in 50 ton lots, and an upward turn is likely to take place any time.

"The nickel market is still lifeless, and very little buying is taking place.

Advances Looked For

"Inquiries for spelter are more numerous than has been the case for some little time, and May, June and July shipment is selling freely. Producers are cautious in making future commitments at present levels, and further advances are likely at any moment. The East St. Louis market closes at 5.05, with both New York and London firm and steady, with an upward tendency. Unquestionably, spelter will be higher before very long.

"Lead is also firm and spot East St. Louis closes at 5¼. The A. S. & R. price for East St. Louis is firm at 5.05 but no large parcels of metal are available at this figure. Lead is not likely to advance much beyond the present price but the producers have the market well in hand and no reduction is looked for in the immediate future."

BUSINESS CONDITIONS SHOW IMPROVEMENT

"WERE I to attempt to describe the conditions now existing, I would to a large extent repeat what I said last year," remarked President Howland of the Imperial Bank a few days ago. Several other statements made were exceedingly interesting, and following are a few excerpts which will interest our readers.

"There are some changes for the better. The cost of manufacturing and the cost of distributing goods has been somewhat modified, but they are still out of line with the purchasing power of the country, and I fear business must still be done without an adequate return. The farmer, too, I am glad to say, has better prospects than a year ago.

"His seeding has been done under fair conditions; he is economizing, getting his labor cheaper, doing his work cheaper, and producing cheaper in practically all respects than last year, and notwithstanding the restrictions on his markets is getting remunerative prices for hogs, in some cases for cattle, and the promise of reasonable returns for grain; he would seem then to have a good chance of coming out with his accounts on the right side; if he does, it will help us all mightily.

"Some branches of mining are yielding returns; the results from woods operations and from lumbering should be better than last year; some of the textile industries are doing better; the trapper, too, I think is getting profit from his furs; automobiles are still selling freely, and in the United States the demand for iron and steel has improved with advances in prices in some cases, which must be reflected here; whether the change is the result of the coal strike or has a more stable foundation it is hard to say. Building is going on briskly, particularly that of dwellings in this city.

"Altogether, although there have been improvements in some directions, I am of the opinion that, while we are getting nearer a stable level, the processes of readjustment must continue for some time before we will be relieved of our anxieties and another lengthened period of what is called 'Good Times' sets in."

MACHINE TAP WRENCHES

(Continued from page 50)

the work required considerable manouvering to secure a proper clamping. Anyone who has done any tapping this way knows how difficult it is to start the tap in straight, it seems to prefer any angle but a right one. The guide A is drilled to slide over the threads of the tap nicely, and has two holes, one at each side into which are driven two drill rod pins B. The wrench C is a solid one with two holes to accommodate the pins in the guide. This idea works better if the wrench is a little easy on the tap square, for this reason; as it is impossible to exert an even pressure with either hand this wrench is always more or less binding a little on one of the pins, thereby keeping the guide close up to the face of the work. The guide remains on throughout the operation there being ample allowance for the tap to travel before the wrench strikes A.

A ONE-MAN MACHINE GUN

The British War Office have recently been testing a remarkable machine gun which is so light that it can easily be carried by one man slung over his shoulder in much the same way as an ordinary rifle. This weapon is capable of firing from 400 to 700 rounds per minute according to the strength of the spring used. The weight, complete with mounting, is only 15½ lbs., and the inventor claims that there is no possibility of the cartridge becoming jammed in the gun. Lubrication of the mechanism is not necessary and the heat of the barrel does not affect the working in any way; in fact the gun will continue firing even though the barrel gets red hot. When the cartridge is fired gas passes through an aperture in the barrel into a cylinder and forces a piston backwards, thus operating a spring which brings another cartridge from the magazine into place.

LARGE CONTRACT TO BE LET SHORTLY

THE Department of Railways and Canals are receiving tenders for the completion of sections 3 and 4 of the new Welland Ship Canal. These are to be closed June 9. The two sections mentioned comprise the heaviest part of the work yet to be done, as they run through rock, and include the erection of several locks. The estimated value of the contract is around thirty millions, and the work must be completed by the end of March, 1926. The locks on this section are the largest in the world, equalling an ascent of 139½ ft. Each lock is 800 feet long, with 28 feet of water on sills. It is estimated that there are about four million cubic yards of rock and twenty-six million yards of earth to be excavated on this section, and about one million five hundred thousand cubic yards of concrete to be laid.

The specifications call for the successful tenderers to purchase all the plant and equipment now owned by the government on the sections valued at $2,500,000 thus making the contract the largest ever awarded in Canada for the expenditure of 30 million dollars for work to be done and for the contractor to pay two and a half million dollars for the purchase of the plant.

These two sections run through the town of Thorold. Since 1919 they have been working on the cost plus system of contract, Doheny Quinlan and Robertson being the contractors, but the government now desire to revert to the unit price contract.

Alex. J. Grant is the engineer in charge of the whole canal, while F. S. Lazier is the divisional engineer for sections 3 and 4. As soon as the contract is let it is said that about 2,000 men will be employed.

A HUGE TYRE MILL

ONE of the most powerful machines in the world for making steel tyres of locomotive wheels has just been installed in a British locomotive works. It is capable of rolling the largest locomotive tyres and it can also produce broad rings up to twelve inches in width. Several novelties have been introduced into the design. One outstanding feature is that the top roll spindle is made to rise and fall, whereas in the ordinary type it is the bottom roll which is movable. Huge as the machine is, both the top and bottom rolls can be changed in a few minutes without dismantling any part of the mill. The mill is driven by special electrical gear which gives every speed from a slow creep up to the fastest possible. The top roll is driven by a four hundred horse power motor and the bottom roll by a six hundred horse power motor, and the driving gear is capable of carrying double load for a considerable time.

About eighty per cent. of the nickel produced is used for the manufacture of nickel steel.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

News From the Industrial Field

Several contracts have been awarded for additional work to the Cambridge St. school, Ottawa, totalling $55,000.

Montreal, P.Q.—The Foundation Co. have taken new offices at 552 Drummond Building.

Tenders up to June 8, will be received by Amable Mercier, secretary of town council, Berthier, Que., for the construction of a concrete bridge.

Fredericton, N.B.—The Imperial Oil Co., Barrack Point, St. John, is considering the erection of an office and warehouse.

Toronto, Ont.—A. J. Latornell, engineer in charge of sewer section, dept. of works, has resigned. George McCarthy who has been engineer in charge of railways and bridges takes his place.

Lethbridge, Alta.—A school to cost $50,000 for Saskatchewan S.D. No. 1,036, and Albert S.D. No. 1,753, will soon be erected if present plans go through. A. M. Jeffers, architect, 210 McLeod Bldg., Edmonton, is preparing the layout.

Aurora, Ont.—Tenders will be received up to June 6, for the erection of addition to school to cost $60,000. The plans are with D. R. Franklin, 2 College St., Toronto, and A. Love, of Aurora will receive the tenders.

R. J. Fuller, chief engineer for J. V. Gray Construction Co., Toronto, has assumed managership of the New London, Ont., office of this concern. Mr. Fuller will however continue to be chief engineer.

Windsor, Ont.—The city clerk will soon advertise for debenture bids for $1,250,000. This is for the erection of the following buildings. Technical school, $666,666, public schools, $65,738.30, street flusher, $12,000, street lighting, $10,535.76, hydro-electric extension, $300,000, and $20,000 for municipal housing.

Tobias Dantzig, Ph. D., formerly instructor of mathematics at Columbia and John Hopkins Universities, and recently research engineer of S. K. F. Industries, Inc., has resigned the latter work to engage in scientific and technical consulting work, specializing in bearing problems and mathematical research of an engineering character. Mr. Dantzig is located in New York at Room 1109 Canadian Pacific Building.

Toronto, Ont.—W. H. Martin & Co., 28 Harcourt Ave., have been incorporated. The name of firm is now the United Building Corporation, and W. H. Martin is president and general manager. Mr. Pillsworth, formerly with Pillsworth & Daly, contractors of Cobourg, Ont., Chas. E. Jex, and Fred Halloway are also included in the new organization. The capitalization is $60,000.

WILL ESTABLISH SALES OFFICE IN TORONTO

THE JOHN MORROW Screw & Nut Co., Ingersoll, Ont., have announced an important policy of expansion. Starting June 1st this company will establish executive and sales offices in Toronto. J. F. MacKay, vice-president and general manager of the company will be in charge, and while he will have his headquarters in Toronto, he will continue to have a general oversight of the company's affairs, spending some time each week at the factory.

J. F. MACKAY

Other changes are as follows:—Lt.-Col. Edmonds, director and secretary, has been made secretary-treasurer, and will reside in Ingersoll. J. E. Hargan, in addition to his duties as works manager, will act as assistant-treasurer. J. C. Adams, the company's Toronto salesman, has been made assistant sales manager.

Two additional travellers have been added to the selling force, Wilbur Detweiler and Lewis Hague, the former covering Western Ontario and the latter being attached to the Toronto office.

Increased demand is evident in all lines manufactured by this firm, and practically the entire force is working on a fifty-hour per week basis, and additional men are being taken on daily. The Ingersoll File Company, a subsidiary of the Morrow Company, has also been enjoying a period of great activity since the first of the year, at present over seventy hands being employed full time with occasional overtime. At present a complete sprinkler system with elevated tank is being erected at the screw and drill plants.

Allison Ridden, Kentville, N.S., is contemplating the erection of a mill.

Field & Patterson, Sawridge, Alta., will erect a saw mill in the near future.

A community hall costing $10,000 is at present being erected at Newcastle, Ont., by the Massey Estate.

Plans will soon be prepared for an addition to Laval Hospital, Quebec. The estimated cost is $150,000.

The Gloves Tanning and Knitting Co., Rigaud, Que., is contemplating the erection of a factory.

A hospital and nurses' home to cost $79,000 will be erected at Pembroke, Ont. Wm. Markus, Pembroke, has been awarded the contract.

The Pacific Meat Co., 268 Columbia St., Vancouver, B.C., is considering the erection of abattoir and cold storage plant which will cost around $100,000.

The general contract for erection of factory to cost $40,000 for Dominion Dress Co. has been awarded to A. J. Cromer, 448 Colborne St., Brantford.

Hon. P. J. Veniot, Minister of Public Works, New Brunswick, says that about $500,000 will be spent on bridge construction throughout his province during the present year.

The Dominion Textile Co., Montreal, is having repairs made to its office amounting to $5,000. J. MacGregor, 44 Close Ave., has been awarded the contract.

Jas. Gordon, 885 Broadview Ave, Toronto, has been awarded general contract for erection of oil distributing station and storage tanks at London, Ont. These tanks will cost $60,000 and will be erected for the Pure Gasoline Co., Toronto.

"We have felt a decided improvement in our business," said Mr. Truman Norton, manager of the Canadian plant of the Wallace Barnes & Co., Hamilton, to Canadian Machinery the other day. "This fact shows," continued Mr. Norton, "that general conditions must be improving, for we handle such a diversified line, catering to all classes of industry, and our books show that these orders are coming in from general sources."

Vancouver, B.C.—A paper mill, to cost $100,000 is to be erected on the north arm of the Fraser river within the boundaries of the city of New Westminster, according to an announcement made by the Westminster Paper Co. This is a new organization backed by United States capital, most of the individuals interested being Wisconsin men. About one hundred men will be engaged, and it is the intention to manufacture tissue and other thin papers from British Columbia pulp for the Canadian and Oriental markets.

The London Life Insurance Co., 424 Wellington St., London, Ont., is considering the erection of an office building to cost around $100,000.

The Western Clock Co. is going to erect a factory at Peterboro, Ont., which will cost approximately $180,000. Sullivan & Fried, 81 Victoria St., have been awarded the general contract.

The steel contract for a time furnace to cost $23,000 for the St. Maurice Lime Co., Three Rivers, has been awarded to the Phoenix Bridge & Iron Works, 83 Colborne St., Montreal.

Victoria, B.C.—The Western Abrasive Paper Co. has been incorporated with headquarters here for the purpose of manufacturing sandpaper. The company is using as abrasive material a hard crystalline quartz from the Prince Rupert district, which has proven to be of hard quality.

Canada may have a new industry here soon. Col. John Jardine, manufacturer of lace making machinery has been visiting Toronto, in fact is making a survey of Canada, with a view of submitting his recommendations to his firm on return to England.

Toronto, Ont.—From 1911 to 1921, a total of $7,702,000 has been voted and $5,777,779 expended on capital account on Toronto harbor, according to a statement made in the House of Commons. On Toronto Island breakwater $400,000 has been voted and $37,441 expended. During the year 1920-21 there were 1,909 steamers with freight entered at customs, and in 1921-22 a total of 1,821 steamers.

Calgary, Alta.—The Rocky Mountain Paint Co., recently incorporated, which has located in this city, controls vast deposits of color-bearing material in the western area of the province and is utilizing these western resources in the manufacture of paints and colors. Arrangements have been made for placing the local product on the western markets.

The Canadian Vickers Ltd., Montreal, has become fairly active since the opening of navigation. The part of yard devoted to repairs is very busy. There is always one boat in the dry dock and it is not unusual to see several waiting their turn tied up in the basin. In fact there is so much repair work offering that the firm is having difficulty in taking care of it fast enough to suit the steamship companies.

Frank Williams, who is now at the Alfred Herbert Ltd. offices at Toronto, Canada, Canadian agents for Holman Bros., rock drill and mining machinery specialists of England, says that his recent trip to Northern Ontario fully convinced him that there is a great future for that section of the country. He says that the results of his visit came up fully to his expectations, and that he was successful in interesting several mining companies in his line. There is considerable activity in Northern Ontario, according to Mr. Williams, and he feels better things are still to come.

Kingston, Ont.—The Canadian Pacific Railway Co. will build a spur line into the feldspar mining district located near Thirteen Island lake, according to latest information received.

The British Metal Corporation has been incorporated with headquarters at Montreal. $100,000 is the authorized capital. C. G. Howard is one of the directors.

Toronto, Ont.—The city council have awarded contract to the American La France Fire Engine Co. of Canada, for varied fire apparatus amounting to $58,-750.

C. P. Thompson, chief engineer of the Koppers Co. is in Hamilton, Ont., conferring with the Hamilton Harbor Commission. Mr. Thompson will erect the new coke oven plant for the United Gas & Fuel Co. also lay out the grounds for the plant.

Montreal, P.Q.—According to reports from the Espanola plant for the Spanish River Pulp and Paper Company, the mill has attained an output of 307 tons per day which is 50 tons per day greater than was originally planned. The entire output of the Spanish mills is working steadily towards the 700 ton per day standing which is expected eventually to be reached.

Grand Prairie, Alta.—Business men who have been identified with brick interests in Edmonton for the past twelve years have completed arrangements for the installation of a brick plant at Grande Prairie to supply the markets of the Peace River country. Suitable clay deposits have been secured and the first machinery has arrived. It is hoped to be producing early enough to supply material for some of the larger structures planned for this year.

The Premier Silk Mills have located at Cowansville, P. Q. This company have incorporated under Dominion charter with a capital of $250,000 preferred stock, and 2,500 shares common stock of no par value. The interests which control the Regal Silk Company of Paterson, N.J., will control the Premier Silk Mills, and a factory has been purchased which is now being remodelled previous to the installation of machinery. This plant is a 3-storey, mill constructed, 100 ft. x 50 ft. The company has also purchased five acres of land adjoining this property to take care of future developments. It is expected that the first unit of 60 looms, out of a contemplated installation of 150 looms, to manufacture broad silks, crepe de chene, etc., and similar goods, will be installed shortly and will employ 100 hands to start with. The company will manufacture both skein dyed goods and piece dyed goods. This is said to be the first establishment in Canada to manufacture this class of material. In this connection it is interesting to note that at Drummondville the Dominion Silk Dyeing and Finishing Company are erecting a plant covering two acres for the purpose of dyeing and finishing silks, either in the skein or in the piece.

The Lackawanna Tubes Ltd., Welland, Ont., have placed an order with the Dominion Bridge Co., Montreal, for the installation of a 7½-ton overhead electric crane in their new plant.

An actual proof of what can be accomplished in the way of building with cement and with other products entirely Canadian is afforded by the completion of the Canada Cement Co.'s new 10-storey up-to-date office building in Montreal, in which cement has been used wherever possible. The project was undertaken partly to gratify a desire of the company to have office premises of their own and also to demonstrate the uses to which their product could be put. The investment has been a large one and, though not made primarily with the object of making money, is likely to prove not unremunerative.

FORT WILLIAM NEWS

The keel of the new freighter Mattewson which is being built by the Port Arthur Shipbuilding Company, has been laid and night and day shifts are engaged upon her construction.

The pouring of concrete into the forms for the storage tanks at the new two million bushel annex to the Northwestern Elevator Company commenced Monday. It is expected the new house will be entirely completed by the end of August. Harnett and McQueen company are the contractors.

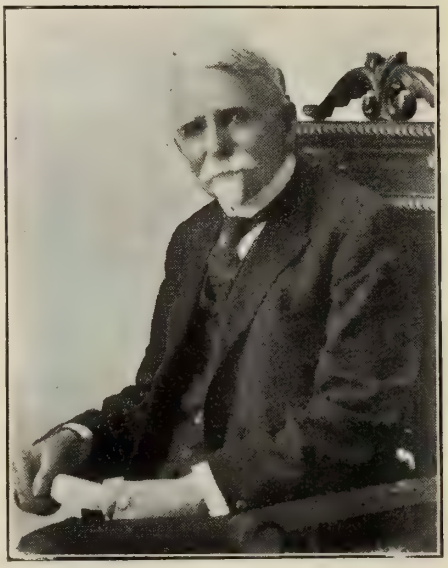
Damage estimated at $15,000 was done to the four storey brick warehouse building and contents owned by the Northern Engineering and Supply Company last week, when fire gutted the structure. Repairs will be made immediately. Sufficient insurance to cover the damage was carried.

Fort William, Ont.—The York Wrench Corporation is the name of a new industry that is to be located in Fort William. It will be housed in the Kelly warehouse, Hardisty Street, and the factory will be devoted to the manufacture of a wrench, the invention of Percy York, a local resident. The head factory of the organization is in Duluth where during the past eight months 16,-000 of the wrenches have been manufactured. T. P. Kelly and H. Frawley, of Fort William, have secured the Canadian manufacturing rights. This tool is fitted with a sixteen inch handle and is so constructed that it can be used quickly and efficiently in cramped quarters. It works on the universal joint system.

Considerable activity still exists along the waterfront of the two cities. Grain shipments by boat continue large and large quantities of package freight are being received from eastern ports. Extensive repairs are being completed to the Canadian Pacific railway wharf adjoining the railway steel dock. The dock is being lowered to the level of the city wharf, immediately up river. Several cargoes of pig iron have been received and two cargoes of binder twine since the opening of navigation. Most

package freighters are arriving loaded but owing to the continuation of the coal strike in the Pennsylvania fields, bulk freighters are arriving light for grain. Only one cargo of coal has arrived here this year. It was loaded in a chartered bottom before the strike. Three ships carried the first cargoes of pulpwood from the head of the lakes last week. Two were bound for Muskegon, and one for Erie, Pa.

Chattels and goods owned by the Palatine Iron and Steel Company, of Chicago, at the old Atikokan blast furnace, Port Arthur, have been seized by bailiff and will be sold at public auction to meet the claims of two former employees for wages due totalling $400. This company's ambassadors arrived in Port Arthur last year and great promises were made. Their ambitions included the putting in first class shape of the old Port Arthur and Duluth railroad running from Port Arthur to the international border at Gunflint Lake, the active development of the Paulson iron mine in Minnesota, the leasing and operation of the old blast furnaces at Port Arthur, and the purchase of 200 acres of land from the city of Port Arthur upon which was to be erected three huge ore docks with a future prospect of electric furnaces, rolling mills and all that goes to make up a huge steel and iron manufacturing centre. Prominent Polish capitalists were supposed to be behind the proposition and there were banquets at which the company officials and the officials of Port Arthur were in turn guests and hosts. Flowery speeches were made and great things promised. Now the bubble has burst. The Palatine Company is said to be defunct. The ancient outlines of the sleeping giant in Thunder Bay are as yet undimmed by the smoke from busy furnaces, and the only commodity around the head of the lakes that ever saw a mine is coal from Pennsylvania.



A movement has been started in the city of Hamilton by Controller Tope to appoint a purchasing agent to supervise the buying of all sundries, the cost of which does not exceed $500. This department would be under the direct supervision of the Board of Control. It is stated that other cities that have organized purchasing departments have effected great savings in the buying of city supplies.

The International Business Machines Co., Toronto, have opened a new showroom at 32 King St. West, in which the three divisions of their business will have ample room for demonstration and service. International time recorders, Dayton computing scales, and Hollerith tabulating machines will be the lines displayed. Speaking to Mr. Morris, sales manager of the firm, he said that they had felt for some considerable time a downtown centrally located demonstration room was essential, and that now they had secured this place, they wished everyone interested to drop in and see them. They will also keep their other store on Yonge St. open.

PIONEER MACHINE TOOL BUILDER DIES IN LONDON, ONTARIO

WILLIAM YEATES, for many years one of London's leading manufacturers, died on May 16th, at the age of 75. He was born in Liverpool and came to Canada when a young boy, settling with his parents in the city of London. He received his early education in the old Union School and afterwards started his apprenticeship with David Bruce to learn the machinists' trade.

Before reaching the stage of a journeyman he enlisted with the seventh battalion of London and fought in the Fenian Raid. After returning to industrial life he served for a time with the

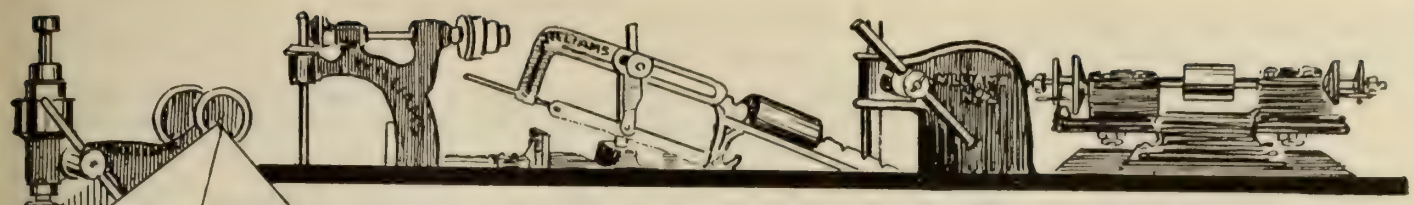
William Yeates

firm of Macpherson, Glasgow & Company of Fingal. He subsequently left this position to form a partnership in the machine business of White & Yeates and White, Yeates and Jolliffe. In 1881 Mr. Yeates founded the London Machine Tool Company. This business was successfully carried on for nearly a quarter of a century at the London plant. The activities of the firm were then transferred to Hamilton where, in addition to the production of machine tools they manufactured many lines of railroad machinery and other equipment. In 1922 the London Machine Tool Company was absorbed by the Canada Machinery Corporation of Galt, the latter concern even removing the greater part of the Hamilton building to Galt. At this time Mr. Yeates retired from active interest in industrial enterprise.

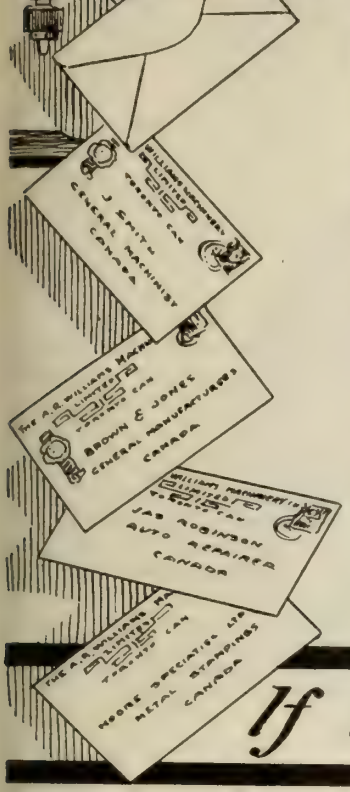
However, the war came along and the need of equipment for the manufacture of munitions was so urgent that Mr. Yeates was induced to accept an order for fifty special lathes. He was then close on to 70 years of age, but undertook this obligation as he had undertaken many others; in the spirit of true patriotism and the love of accomplishing something worth while. At that time he had no shop of his own but renting one, installed the necessary equipment for the manufacture of the shell lathes, which were turned out in record time, several hundred being made altogether. Mr. Yeates was greatly interested in many other activities, having served several times on the Western Fair Board, on the local school board, and took a keen personal interest in the development of technical schools, being one of the pioneers in this movement in the Province of Ontario. The passing of Mr. Yeates removes one of the pioneers of machine tool building in Canada. The city of London is still using a six million gallon cross compound steam driven pump constructed under his supervision back in the early nineties.

In his treatment of employees the late Mr. Yeates might be termed an employer of the old school. While exacting in his requirements all the men who worked with him were his friends. To the apprentices — for apprenticeship under him was a privilege very much sought after—he was both mentor and father—and they lay the groundwork of their mechanical experience to the very thorough training received in his shop. Many of these men are now owners of their own plants or occupy important posts in large industrial enterprises in the States.

DEATH OF ERNEST SOLVAY



Ernest Solvay, the inventor, reputed to be the wealthiest man in Belgium, died suddenly at his home in Brussels on Friday morning, May 26th. Mr. Solvay will be remembered as one of those who were seized as hostages by the Germans on their entry into Brussels during the early stages of the war. As an inventor he was chiefly interested in chemical research and as such he became world famous in the metal industry field as the inventor of the "Solvay Process" of making low-sulphur foundry coke from ordinary soft coal which had formerly been unsuited. Had he accomplished nothing but this his name would be worthy of a prominent place in history.



PASSING OF WILLIAM SHEARER

Wm. Shearer, who served for a number of years as superintendent of the James Smart Mfg. Co., died a few days ago, at his home in Brockville, Ont. Mr. Shearer has held various positions since his retirement from the James Smart Co., and in addition to being engaged in the real estate business has been secretary-treasurer of the board of trade, and held other local positions.

Canadian Electric Castings Co. of Orillia, are constructing a new building. They make electric furnace products, largely for mining and cement industries; also bronze, brass, iron and steel castings.

Approximately eighty per cent. of cobalt is used in the making of stellite.

Perhaps our experts can help you?

YOU are invited to call on us for any sort of service in connection with machinery of any kind. The staff of experts comprising our Service Department are specially trained to serve you and can be relied upon.

We can also fill any requirement for machinery (new and reconstructed) from our immense stock of nationally known products. You will find our prices right and that we live up to our reputation for fair dealing.

Let us put your name on our mailing list for our monthly Machinery List.

Ontario Distributor: **H. A. Harrison, 220 King Street West, Toronto, Ontario**

Fisher Motor Co., of Orillia, manufacturers of die castings and metal stampings are taking over new premises to take care of their increasing business.

J. Walter and Sons, manufacturers of wood fibre products will erect a new factory at Kitchener. The new plant will treble the output and take care of the rapidly growing export trade of this firm.

The Canadian Wire and Cable Co. will establish a plant in Vancouver, B. C. This plant will take care of the company's market in the west. It is stated that about 400 men will be employed at the Vancouver factory.

The H. H. Robertson Co., Sarnia, Ont., report an improved demand for their roofing and siding products used largely for manufacturing plants. Among recent contracts are squares for Page Hersey Co., Welland, and the new building of the Lackawanna Tube Co., Welland.

"Business is improving," according to Mr. Morris, sales manager for the International Business Machines Co., Toronto. Computing scales are the feature at present, but as several factories have recently engaged more help, they are securing some time recorder business as well. "The situation is much easier, and the added interest in recorders can be accepted very much as a thermometer of business improvement," concluded Mr. Morris.

Announcement is made that the McClary Manufacturing Co. of London, has commenced operating again with a full staff of men and on full time. J. J. Foote, who made the announcement, states that times are slowly but steadily improving, and he looks for general prosperity in the not far distant future. McClary's has always been the barometer of conditions in London, and the announcement of the return of the plant to normal conditions of business is good news to the citizens.

TWO IMPORTANT FIRMS HAVE JOINED FORCES

The National Electro-Products, Ltd., and the Dominion Oxygen Co., have amalgamated. This consolidation becomes effective immediately. The Dominion Oxygen Co., takes over the plants, patents, goodwill and contracts of the National Electro-Products, both companies operating under the name of the Dominion Oxygen Co. By combining forces, they intend to add still further improvements to their service, stabilize the products, thus making possible a steady supply.

E. G. MacKay, lately superintendent of the steel plant of the Scotia Steel and Coal Co., at Sydney Mines, is retiring and was presented recently with a gold watch and address by the office staff. Mr. MacKay leaves shortly for Pittsburg, where he is expected to take an important position with the Lackawanna Corporation. A. C. Fraser, of the Scotia staff at Sydney Mines, leaves shortly on a two months' vacation trip to the west.

BRITISH MOTOR LINERS

Excellent results continue to be obtained by the oil-driven ships constructed in Great Britain. Recently a large passenger liner equipped with oil engines completed a round voyage from the United Kingdom to India and back; and the commander of the ship reported that the engines "ran like a sewing machine." Even at the present heavy price of oil the voyage showed a considerable economy in the cost of fuel in comparison with coal. The passengers benefited from the absence of coaling on the voyage and by the minimising of vibration. The daily consumption of oil at 14 knots was less than 18 tons. Another British oil-driven ship proved on her trials that she could run at 13 knots on 16 tons of oil per day. The oil is carried in the double bottom of the vessel and there is sufficient capacity for a voyage of 30,000 miles.

A NEW BATTERY LOCOMOTIVE

The use of locomotives driven by electric batteries is rapidly developing in mines and in connection with civil engineering, as well as in factories and on railsidings. In fact the popularity of this type of locomotive for special purposes has led a leading British locomotive firm to devote the attention of experts to the problem of improving the efficiency of the machine. A new type of mechanism was accordingly devised and recently tested with remarkable results. It was found that for a certain amount of actual hauling work done by the locomotive only half the usual battery capacity was required. The control arrangements are extremely simple and do not involve the complicated resistances generally required. Only one motor is used. One very useful feature of this novel design is that the locomotive automatically "regenerates" with a high degree of efficiency. That is to say, when the locomotive is running down hill or being brought to a standstill the motor produces electric power which goes to re-charge the battery. Another point of importance is that ball bearings are used throughout as an additional means of saving power. Hitherto locomotive engineers have looked askance at ball bearings for heavy machines, but the pioneer courage of this British firm seems to be fully justified by results.

HORSE POWER ELECTRIC BOILER

To many people it will seem absurd to use electricity for making steam; but this is actually being done—and for a very good reason—on British railways. The railway systems in Great Britain are gradually being electrified where the conditions are favorable; and the result is that in certain routes steam haulage will be at work on one portion and electric haulage on another. The usual practice is to heat steam trains with the steam from the locomotive, and obviously this method cannot be continued when the steam locomotives are replaced by electric locomotives. Ex-

Rockwell Rotary Automatic Furnaces in series for a three-operation heat-treatment

A WELL-BALANCED DIE HEAD

Geometric Style DD
For Hand Operated Turrets

Yields to Adjustment
Resists Inaccuracy

Faulty Turret adjustment is common and causes serious trouble in cutting Screw Threads. The Geometric Style DD Die Head for Hand-operated Turrets, with its compensating spring mechanism, not only functions perfectly itself, but overcomes any inaccuracies of adjustment of the Turret. The Die Head yields as it comes in contact with the work, allowing the Chasers to start the thread properly.

In perfecting a Die Head for certain Automatic Screw Machines, features were developed that made the Die Head quite as desirable for Hand-Operated Turrets, and as a result the Style DD for Hand Operated Turrets has been added to the Geometric Die Heads that have just the right features for the varied requirements of machine and work.

Latest improved equipment is telling the story of production in busy shops.

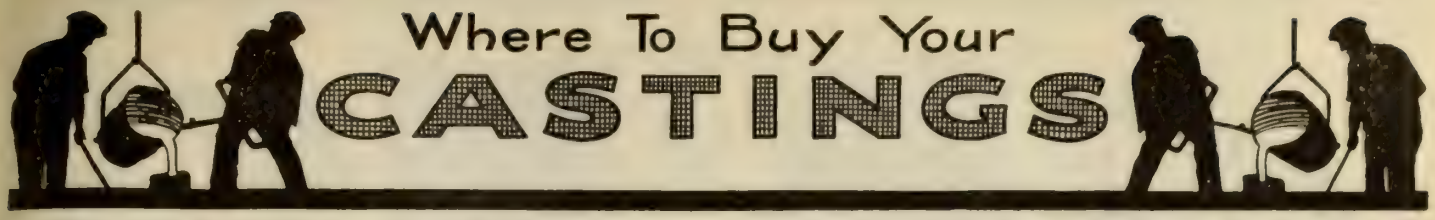
In order that the announcements of your wants, machinery for sale, etc., etc., shall not be delayed, please try to have them in our office with the Tuesday morning mail.

Canadian Machinery

$67.60 Per Year



How much time in a year do you spend soliciting business for your shop? Half an hour a day? All right! Half an hour at a 6-day week comes to 3 hours a week. 3 hours a week at 52 weeks in a year amounts to 156 hours a year.

How much is your time worth—$2.00 an hour? To make sure we'll say $1.00.

That means you spend $156.00 worth of your time each year looking for business. This page is read and considered valuable by the majority of plant superintendents, purchasing agents and managers, both large and small, all over this Dominion. A one-inch card every week with a REAL message in it will do more for you than you can do for yourself. We only charge one-half of what it would cost your business if you were to use your own time.

	Per year	
RATES:— 1 insertion $1.50	$ 1.50	[ ]
26 insertions $1.40 each (every other week)	36.40	[ ]
52 insertions $1.30 each (every week)	67.60	[ ]

Put a cross alongside the space you want to use. Attach your advertisement to it and send it in to us.

DO YOU MISS IMPORTANT NEWS?

WE read the newspapers of Canada and the United States as a business. We can supply you with valuable news on any subject, whether you are interested as a manufacturer, wholesaler, retailer, advertiser, editor, farmer, or politician. We send you these original clippings, which keep you posted on current events, changes in business, prices, construction news or any special information you wish us to gather. This service costs you little and is valuable to any business. Write for prices and name your subject. Canadian Press Clipping Service, 143-153 University Ave., Toronto.

—and when the cutter was taken from the furnace he found—

That its cutting edges were hard and clean—no scale—and did not require to be ground. It meant much to have their edges clean and true to shape.

That's the kind of results you can get with Hoskins Electric Furnaces. The heat is clean and the temperature control is right under your thumb. The man who does the heat treating does not have to fuss around trying to get the right temperature—he takes care of the **tools,** and **not** the **furnace.** He gets greater production and better tools.

Hoskins Electric Furnace will save you money. Not just for tool rooms are they an economy but wherever metal is heat-treated.

Tell us the work you want done and ask for catalogue No. 122.

To Oxygen Users
ANNOUNCEMENT

ONE of the largest organizations of its kind on the continent is created by the amalgamation of the extensive resources of

National Electro Products Limited

with

Dominion Oxygen Company Limited

This consolidation becomes effective immediately. The Dominion Oxygen Company Limited takes over the plants, patents, goodwill and contracts of the National Electro Products Limited, and will operate them under the name of the Dominion Oxygen Company Limited.

This union of the two companies will be of material advantage to all users of oxygen—it will effect stabilization of product — assure steady supply—and make possible important improvements in service.

It is sincerely hoped that the patronage given in the past to these two concerns individually will be extended to the new organization.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

Confessions of a She-Politician

"I MYSELF, am a victim of the vote for women," writes the anonymous author of this very frank article discussing "Women in Politics."

Rule by Oratory Is Ended

J. K. Munro's monthly feature discussing all phases of Canadian politics as he observes it from his eyrie at Ottawa; without bias, without prejudice, and without any particular axe to grind.

This simply **had** to be an anonymous article because the writer is well known throughout several provinces of Canada for her activities in politics. This article is a startling admission from her pen of many things which the women of Canada may think, but few are able or honest enough to place on paper. The writer admits that the life of a woman in politics is not all "a bed of roses" and also is very candid in agreeing with some critics who say that women can never take as responsible a place in politics as men. This article also indulges in some rather severe strictures on the feminine sex, really amazingly penetrating criticism, and should be read with avid interest by every woman and most of the men in the Dominion. It is a human document, guaranteed authentic by the Editor.

LANDIS

The Operator knows that a Landis produces

A workman is judged by his ability to produce. Therefore, every grinding machine operator, knowing that he can only reach his maximum when he is using equipment that reflects his skill and responds to his trained touch, is anxious to work on the very best machines. That is why *Landis Universal Grinders* are favorites among the workingmen.

Landis Grinders are capable of fine adjustments, and they *hold* the adjustment! They are easy to operate and have many features which make for speed and accuracy. In the tool room or out in the machine shop the "Landis" will take care of every grinding problem.

The *Landis Universal Grinding Machine* will help you increase production, reduce spoilages and save time, money and labor.

There's no Heald in This Plant

Many a repair shop proprietor and small machine shop owner was forced to give up the struggle in the year just past, and a big factor in his failure was the lack of proper equipment to cope with present-day needs.

If the repairman is not in a position to do this work and if there is no one in that neighborhood who has a Heald Machine to handle it then the motor owner will take his work where it can be done.

Particularly is this true in certain localities where there is centrally located a small machine shop, repair shop or welding concern who do a large amount of general repair work, but to get all the potential possibilities they should be able to regrind. It creates so much satisfaction and cures so many motor troubles that the results are that every customer immediately becomes a big booster.

The Heald Style No. 55 is especially built for such shops, simple, moderately priced, mechanically perfect and with a range that will handle any kind of block regardless of style or size. It comes fully equipped, ready to go to work.

Take an inventory of the automobile owners in your locality. Ask the local garage man how many requests he has for regrinding and then get in touch with us and we will furnish facts and figures, also prove the soundness of installing a Heald.

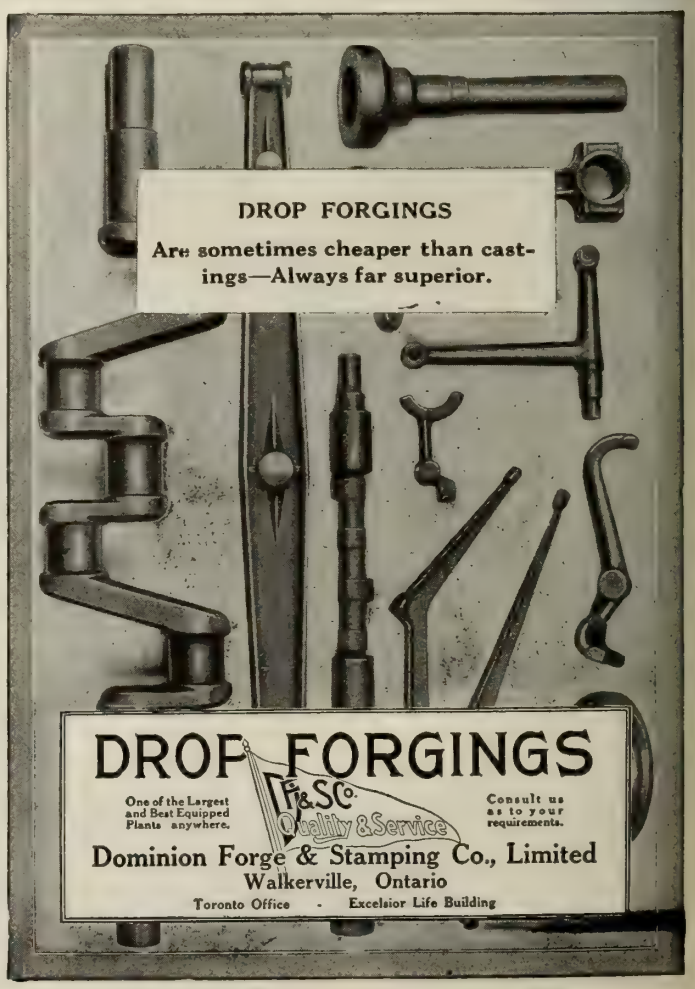
The only Self-Draining Steam Pump Made in Canada

Minimize Pump Troubles!



YOU don't have to put up with troublesome and costly pumps—pumps that leak and are in constant need of adjustment.
Your solution is in the Hepburn Patent Vacuum Pump. It requires very little attention; there are no tappets or levers to give trouble; the valves are very accessible and the long strokes assure a decided steam economy.
Write us for a complete list of features as well as particulars of Hepburn Engines, Compressors, Cranes and other Machine Shop Equipment. Information will be freely given.

ARMSTRONG

Bent Tail Lathe Dogs

They Stay With the Job

With Headless Screw

With Square Head Screw

Canadian Agents:
A. R. WILLIAMS, Toronto
WILLIAMS & WILSON, Montreal

The specially tough grade of open hearth steel from which these dogs are drop forged gives to them the stiffness and tensile strength so essential in a good lathe dog. They are designed to stand up to the severest work—moreover, they do so.

The screws are made of alloy steel, hardened at the point, the improved shape of which renders them less liable to "flange" or upset.

Welland, Ont.

Sheer oversight is sometimes responsible for a file being kept in use after its keen-cutting edge is gone.

The result is loss of efficiency, wasted time and effort.

The remedy is: discard a file at the first hint of wear, and buy a new one.

Best results will be obtained by specifying one of these famous five brands, the standard for over fifty years.

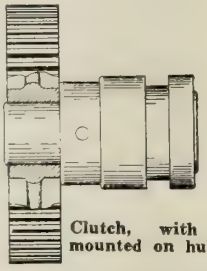
THE JOHNSON FRICTION CLUTCH

IS USED ON THE

PEERLESS DOUGH MIXER



Courtesy of the Peerless Bread Machine Co., Sydney, O.

A No. 4 single clutch is used to facilitate starting and stopping.

Lubrication is a necessity for all running bearings and frictions and an occasional application is all that is necessary.

Adjustment of the Johnson friction clutch is simple. A small screw moves two taper blocks in toggle levers, giving greater expansion to ring — thus more gripping power.

Clutch, with gear mounted on hub.

The Johnson friction clutch is a small, compact and very powerful device for machinery of all kinds where medium or light power is transmitted.

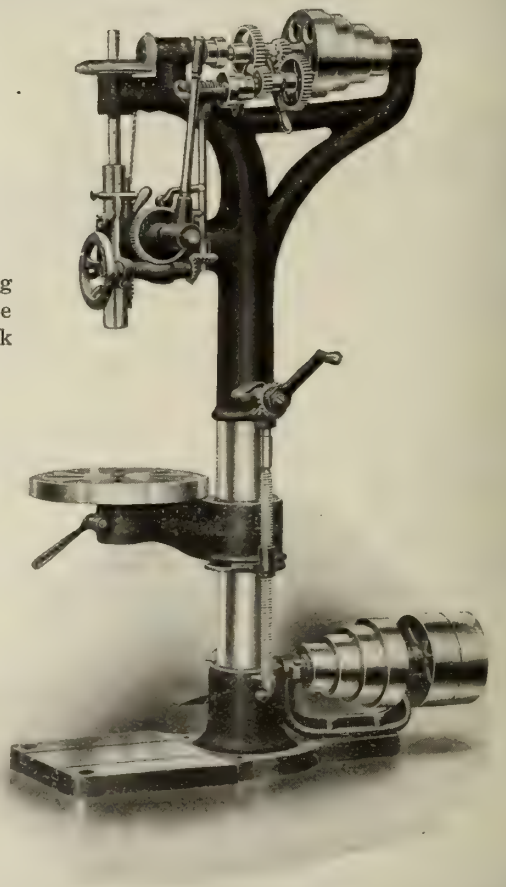
McDOUGALL



New and Improved 20-INCH DRILL

This new addition to the McDougall line is a profitable all-round drilling machine. Its parts are solid, simple and compact, the kind of machine to suit the demands of present day production. Equipped with back gears, power feed, automatic stop and quick return.

This machine will drill 1¼-inch holes in steel and 1½-inch holes in cast iron from solid metal and will bore up to several inches in cored holes.

With the power feed and automatic stop a number of them can be used in gangs, greatly reducing the cost of labor. Made without back gears or self-feed if desired; or with reverse motion. The reverse motion is simple and effective, requiring no extra belts.

Quality work at low cost of production follows where this machine is used. Send for complete description.

Interesting Examples of Multiple Fixture Work

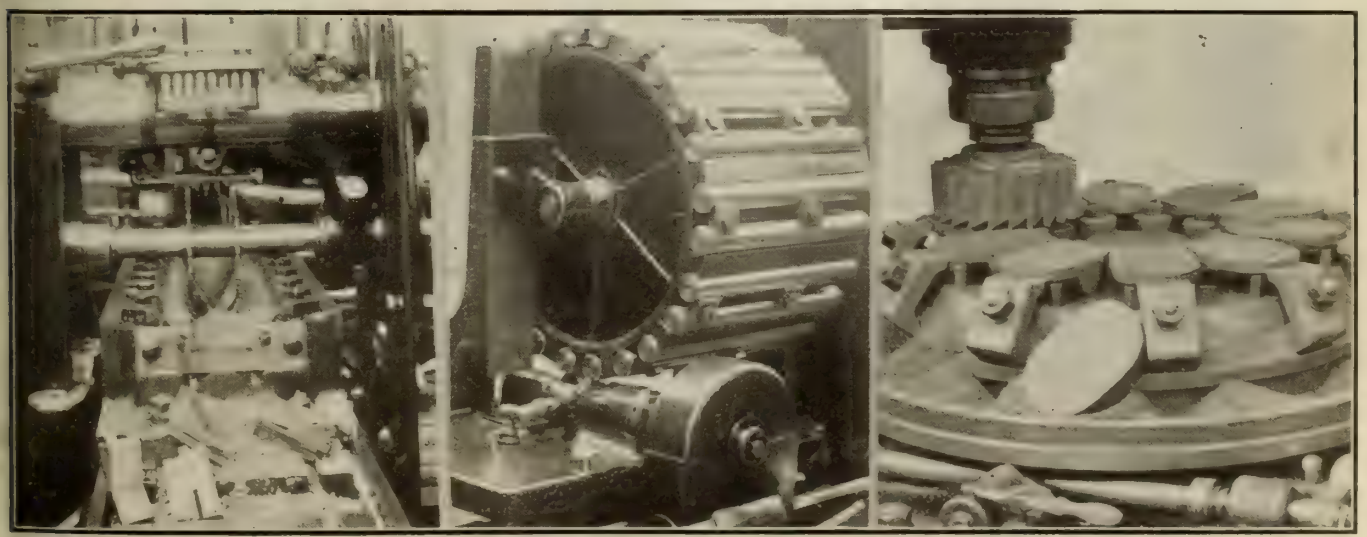
Minimizing Non-Productive Time—Conserving the Energy of the Operator—Making of Parts in Large Quantities Demands Adequate Machining Facilities—Magnetic Chuck Permits of Rapid Setting

By J. H. RODGERS.

MODERN manufacturing methods to-day are tending more and more to the elimination of unproductive time, and the utilization of processes and machine equipment that will relieve the operator of the physical effort required in performing unnecessary manual labor, as related to the work upon which he is engaged. The chief aim of machine tool builders is to incorporate improvements in their product that will spell economy. The human element is the one outstanding factor that makes the solution of the industrial problem so difficult, and yet it is a portion of this very element that is making it possible to overcome many of the intricate phases of manufacturing that are confronting us at the present time.

Multiple Fixtures

One of the most interesting developments of recent years is the rapid progress made in the design of tools for multiple machining, both in the way of fixtures and tool cutting heads. The continuous method of cutting is the feature most desired in the machining of metal parts, and in plants where large quantities of any particular piece is produced, the question of multiple or uninterrupted operation is of prime importance and should receive the careful consideration of executives before deciding on the methods to be adopted for performing the different detail operation. Very frequently the jigs and erations. Very frequently the jigs and keep down the initial cost of manufacture. Where the output is comparatively small it is often well to go cautiously in the making of equipment for duplicate production as the first expense may smother the profits estimated on the work; but on the other hand, the making of parts in large lots demands adequate facilities for taking care of the output on economic lines.



Non-Productive Time

It is difficult to calculate with any degree of certainty just what is non-productive time, as the value of this factor varies in relation to the problem. In the operation of metal cutting tools the productive period is frequently designated as that actually occupied in the cutting of the metal, but there are various details of manipulation of machine and tools that must be taken into account and which are essential to production. The chucking of the work, for instance, must be properly accomplished before cutting can be commenced. Tools must be ground, set and adjusted before starting the cut. Many other minor but none-the-less important factors must be considered in attempting to find a definite answer to the non-productive phase of manufacture.

Continuous Cutting Operations

What would appear to be the livest topic in advanced shop practice is the possibilities of the multiple fixture whereby continuous cutting can be carried on. What is most desired is that the machine should be kept at work all or most of the time. The cost of a multiple fixture may sometimes seem excessive but where the volume of machining is ample to cover the outlay the

Information and views in Fig. 1 by courtesy of Alfred Herbert Co. Those shown in Fig. 2 through the courtesy of the Heald Machine Co.

Left—Milling roller slides for roller steady turners on Herbert hexagon turret lathes. Centre—Continuous milling of splines on gear cutter. Right—Continuous milling of pump covers.

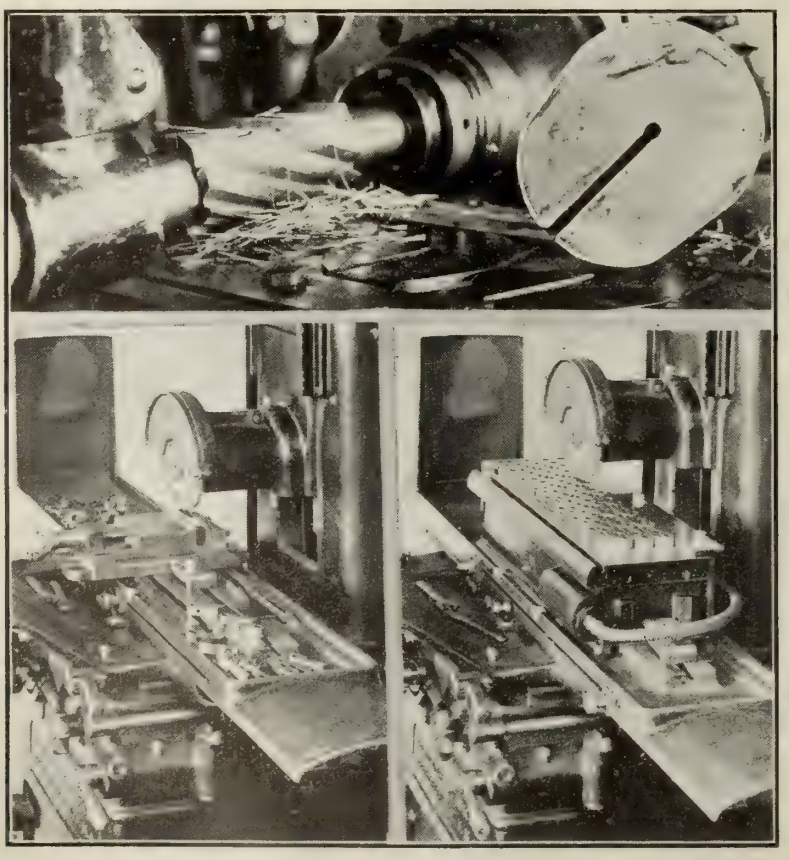
making of such equipment is the essence of economy.

Saving Time By Slitting

At the left of Fig. 1 is shown an interesting operation on the roller slides used in the roller steady turners on the Herbert hexagon turret lathes. The material for these slides is made of 5 carbon steel, heat treated. One of the finished slides is shown at the end of the table, and the operation here shown completes the removal of the wedge shaped piece shown on the table in the lower foreground. Instead of milling the metal completely away, it is removed by the intersection of two thin slots produced with side and face cutters, the second cut being the one illustrated. The fixture holds 40 pieces, and the side and face cutters are 8in. in dia. by ¼in. face. For this operation a feed of one inch per minute is employed, the limiting factor being the strength of the cutters.

Special Splining Fixture

The fixture shown in the centre of Fig. 1 is worthy of special notice. It is used for cutting the splines in shafts. The milling operation is continuous and performed on a gear cutting machine. The fixture is mounted on a work arbor, constructed for holding 24 shafts at the one time. Two splines are cut simultaneously with a pair of 3in. dia. slotting cutters, running at 80 r. p. m. The feed is 13/16in. per min., and the dimensions of the keyway ⅜in. wide, 3/16in. deep and 9⅜in. long. During the cutting operations the workman is loading and removing finished work, so that the machine operates continuously and several may be tended by the same operator. Fixtures of this character are a paying investment to any plant producing parts in large quantities.



Continuous Verical Milling

Another milling fixture that permits of uninterrupted facing operations is shown at the right of Fig. 1. The work here is performed on a vertical milling machine and the fixture is secured to the revolving table. It will be noted that each cover is clamped by the operation of one nut, the clamp being so designed as to come below the level of the machined surface. The inner bearings against which the covers are clamped are threaded in such a manner as to pull the work down firmly on the locating pins. The cutter is 7in. dia., running at 30 r. p. m. and the output is 40 pieces per hour.

No Clamping Necessary

Another feature of interest in regard to modern methods is the increasing application of the magnetic chuck to the holding of work while the machine is being carried on. Primarily developed for holding work while grinding, the magnetic chuck is now receiving greater attention in connection with other phases of machine shop operations. At the top of Fig. 2 is shown a milling operation where the work is supported on a Heald magnetic chuck. No vise or straps are necessary. The plates, which are being milled, have previously been blanked out in a punch press from metal 165in. thick. They are held by the magnetic chuck and approximately .020in. is milled from each side, reducing the thickness to .125in. The five plates end to end make a milling surface 4in. wide by 21in. long. The cutter is 3½in. dia., and is run at 350 r. p. m. The error is limited to .005in.

The grinding machine is rapidly becoming an economic factor in the production of parts that until a short time ago were machined in an entirely different manner. The two lower views in Fig. 2 illustrate distinct methods in the facing of the sides of small pawls. As shown at the left this was formerly done by holding the work singly in an ordinary vise, one being ground at a time. As shown at the right the pawls are now placed on a magnetic chuck 56 being surfaced at the one setting.

Top—Milling thin sheet steel punchings held on magnetic chuck. Lower left—Grinding pawls held in vise. Lower right—Surfacing 56 pawls held on magnetic chuck.

A RUSTLESS IRON

An iron which not only possesses rustless properties but also can be worked cold without any trouble whatever are the characteristics of a rustless iron now being made on a commercial basis by J. J. Saville & Co., Ltd., Triumph Steel Works, Sheffield, samples of which we have recently examined. The Saville rustless iron can be bent cold through an angle of 180° without fracture, and the material is supplied in the soft condition, in which it is rust-resisting without any heat-treatment or hardening process after working, no matter to what purpose or in what shape it may be required. The only thing the user has to do is to treat the rustless iron in the same manner as he would brass and copper for the same purpose, that is to produce a bright surface and good polish on the article whatever it may be. This he can do by any method that may be convenient. It is claimed, says a writer in British Machine Tool Engineering, that the Saville rustless iron will take a polish equal to that obtained on electroplate and, in the soft condition, remains impervious to rust or tarnishing without any attention being given to it. The possibility of utilizing it for those machine-tool parts which, by reason of their contact with cutting compounds are subject to corrosion, will doubtless occupy the attention of machine-tool makers.

Another important property of the new material is that it can be manipulated into any shape or section by any process of cold working, such as cold stamping, cold pressing, cold rolling, cold drawing, or spinning, and, of course, by hot drop stamping or forging. The production of an iron capable of withstanding, without puckering or cracking, the most severe cold work and of being made by this work into intricate shapes, such as ornaments, beading, lamp bodies, and ship's fittings, is certainly a remarkable achievement. The physical properties of the material cover:—

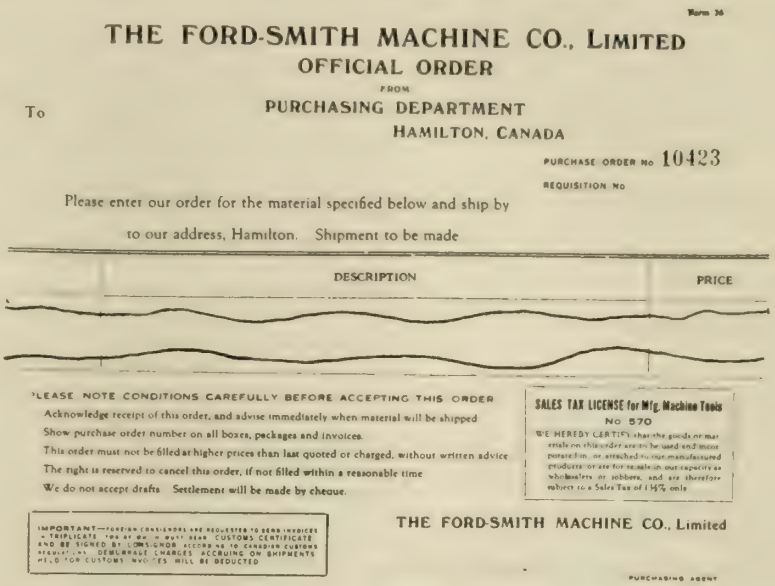
Tensile strength (approx.) 40 tons per sq. in.
Elongation (approx.) 25% on 2 in.
Reduction of area (approx.) 60%.
Brinell 150.

How to Figure Successfully on Special Work

Simple Method of Keeping Track of Costs When Making Special Machinery and Estimating on Contract Work—Type of Forms Used—How Future Orders Are Dealt With

By J. H. MOORE.

Based on interview with P. Ford-Smith, general manager of the Ford-Smith Machine Co., Hamilton, Ont.



IN these days of keen competition it is the firm who tries in every way possible to reduce expenses and increase production that shows on the right side of the ledger at the end of the year. Owing to present conditions, several firms who previously handled only standard lines, are going out into the highways and byways in search of special work. Anything to keep the staff intact.

Often this change of policy causes confusion in cost keeping, with the result that the management is none too sure of the margin of profit. In fact they sometimes are doubtful if they even cleared expenses, especially on contract work. Keeping these points in mind, the following information should be extremely valuable, for the system described is one that the Ford-Smith Co. are at present using with splendid success. They know exactly where they stand. Guess work is eliminated, and not only do they benefit themselves, but the customer also feels that he is getting a square deal.

The type of work handled by this firm can be divided roughly into three different classes, viz., small jobbing work, repair work, etc.; special machinery tools and jigs, and standard grinders and millers.

In the case of small jobbing work, this is generally described on an order as shown at Fig. 1. This is issued from the main office on their regular shop order form and instructions are generally left in these cases, between the firm desiring the work, and the shop superintendent of the Ford-Smith plant.

Very often the drawing office, though receiving a copy of the order as usual, have nothing to do with it, simply getting the copy for record purposes.

THE FORD-SMITH MACHINE CO., Limited

PURCHASING AGENT

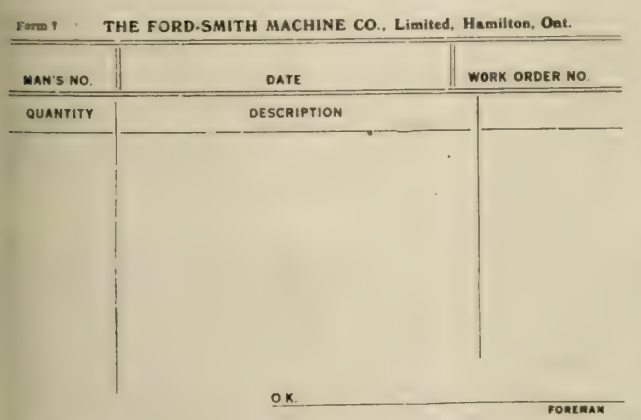

Fig. 2—Showing the style of official order used on special orders.

In the case of special machinery, tools, jigs, large dies, etc. the order goes through the office in the regular way. Each department, that is, the superintendent, chief engineer, shipping clerk and purchasing agent, all receive a copy. The material, except parts coming from the stock room are requisitioned in the drawing office, and go down to the purchasing agent. Prices are then enquired for, the material is ordered and brought into the factory as quickly as possible.

On the class of work manufactured by this firm, delivery is very important. If necesary, detail and working drawings are made in the drawing office which later go down into the shop after patterns are requisitioned. Copies of all requisitions made out by the drawing office go to the superintendent as well as to the purchasing agent, so that there shall be no overlapping, and also that the superintendent shall know exactly what is happening in regard to the matter for the job in hand.

The purchasing agent in writing out his official orders, makes copies as shown in Fig. 2, one of which goes to the superintendent so he is immediately informed that the material is ordered, and when he may expect it. This allows him to arrange his work. The original goes to the firm from which they purchase the material, and copies also go to the drawing office and shipping clerk. Thus we have an original, and three copies.

When special work, such as jigs, tools, dies, etc., are being made there is necessarily considerable intercourse and explanation between the drawing office

and factory, but this is thoroughly understood, and no friction occurs. Everyone works in harmony, the idea being to produce at the lowest possible cost.

Standard Machines

When working on standard machines, the regular order form is made out in office, and copies distributed as usual. These machines come out of stock, so that really only the superintendent and shipping clerk are interested. If an order should clear out the stock, a new stock order is made out to the factory ordering them to make a certain number of machines for stock purposes. In this regard maximum and minimum quantities are provided.

ORDER ACKNOWLEDGED .....
HURRIED .....
SHIPMENT PROMISED .....
.....
.....
ORDER COMPLETED .....

When a job is completed, the shipping clerk makes his final remarks on the original order and returns it to the office. The drawing office and superintendent do the same with their copies. The purchasing agent attaches his vouchers of costs to his copy, then the sales manager gets a complete record of the costs and anything regarding each order. These are tabulated and the costs are always available. The invoices are then put through, if the work is on a time and material basis. Should the work be on a contract price, it is invoiced at this price, and a comparison made between the estimates and the actual costs. If there is any particular difference, the whole matter is very carefully sifted through to see where the estimate was inaccurate, or whether there were some special circumstances which made the costs vary from the estimate.

Fig. 3 shows the style of form used by drawing office when requesting material from the purchasing agent. A copy of this requisition is sent to the superintendent, and a copy also remains in the drawing office files.

This completes a simple but very efficient system, once an order has been completed on contract price, the firm knows definitely whether they lost or made money on the order. In the event of the profit margin being high, they give the customer the benefit of this on future orders of similar character, quoting a lower price. They also allow a reduction on future orders when the first contract price had to cover cost of patterns, etc. We know this fair dealing policy exists, for in discussing the matter with the manager, Mr. Ford-Smith, we touched upon several cases where this had been done.

After making repairs or adjustments to countershafts or hangers be sure and remove all tools. This will prevent the chance of accident.

It Does Not Pay to Mix Sport With Daily Work

YOUR article and editorial of noon-hour problem, which appeared April 27, fully coincides with my views," writes a well known manufacturer who prefers his name deleted. "I think the man who wrote this showed a great knowledge of the subject and a real understanding of same," he continues, but let this plant owner speak for himself from now on.

"I have talked with the managers of one or two large concerns on this subject, firms who have had their football teams and their baseball teams, whose successes have been written up in the newspapers, and they tell me that in very short order, the success of the baseball team or the success of the football team, is the sole topic of conversation and pretty nearly the sole thought going all through the plant, to the great detriment of the work.

"This applies particularly to sports. We have the same thing here in our Collegiate Institute. We have a track team which is probably second to none, taken all around, in the whole continent. The papers have had the boys' photographs in, and up to the advent of the new principal a few weeks ago, about the only thought of the students was about the track team.

"I do not think that a firm in business should take any active interest, as a firm, in sports. If they like to subscribe to the various teams in the city and generally encourage sports, that is alright, but as a company, I think that they should not encourage sports amongst their employees.

"I think the proper thing for the noon hour is to have a real good rest room with a man in charge who can see that the furniture is not abused, with plenty of books and periodicals around for reading, and also to see that the place is kept quiet for the men who want to read, and also to see that there is no discussion of matters detrimental to the interests of the company. If men want to discuss such matters, they should at least have the decency to do it off the company's premises. Other than this, I do not think that the company should take an active part in filling up the men's spare time with their own ideas.

"As a general thing we have found that men who are actively interested in sports, even heads of departments, are not generally sufficiently engrossed in the firm's business, and while we thoroughly understand that men must have recreation, and that it is very good for them, outside interests, particularly sports, are altogether too engrossing for a man to make advancement in his work. The only welfare work we do is our group life insurance by which every person in our employ is covered, and we have found this a great advantage to the men."

Another gentleman who has charge of several hundred men remarks that his firm does not know the meaning of welfare work. He says that all things done for the men come under the name of service, and in explanation remarks as follows:—

"When a man is going along nicely, all happy and in no trouble of any kind, there isn't anything we can do for him, but the moment he bumps into trouble we are right there to do all we can to help him out. And we help him no matter what the trouble is. After he is clear and back onto his feet we may have a severe reckoning with him and he may go to work somewhere else but only after he has been put on the right track. We do not believe in jumping on his neck when he is flat on his back.

"If we were a company making some product that needed some cheap advertising, we would probably have a ball team, and charge its expenses to the advertising department. However, we do not need to boost our goods publicly and are in the plant to produce material, not turn working hours into play time.

"We made one stab at sport, but it wasn't a success. As soon as our help showed signs of wear and tear, we cut out the game. No one was peeved, because down in their hearts they knew they had been overdoing it. In the winter months we have a bowling league, but after hours. We go down town in the evening, and it does not interfere with the work.

"Every year we have a picnic, and occasionally a dance, but all outside of working hours. We believe the men are at our plant for a definite purpose to get the work out, and are happy when they can accomplish that purpose. Welfare work may be all wrong, service work is good stuff, at least that is how we look at it."

"We do considerable welfare work here but have never considered any particular arrangement for the noon hour entertainment of employees," says W. C. Franz, president of the Algoma Steel Corporation, Sault Ste Marie, "and I entirely agree with the writer of the article in your April 27 issue, that it is of very little importance. Some of our employees are on continuous operation and those who are not occasionally find some kind of entertainment, but so far as the company is concerned we have never felt there would be any particular benefits in arranging any entertainment at that time."

As the wrong application of brakes has the effect of greatly increasing the power consumption of electric cranes, the motors should not operate against brake friction, but should be released from it when the controller handle is moved to the first notch of the starting position.

Give Consideration to Small Shop Layout

Advantages Often Derived by Rearrangement of Equipment—Keep Product Moving in One Direction—Proper Location of Different Departments a Factor of Economy—Keeping Tab on Work

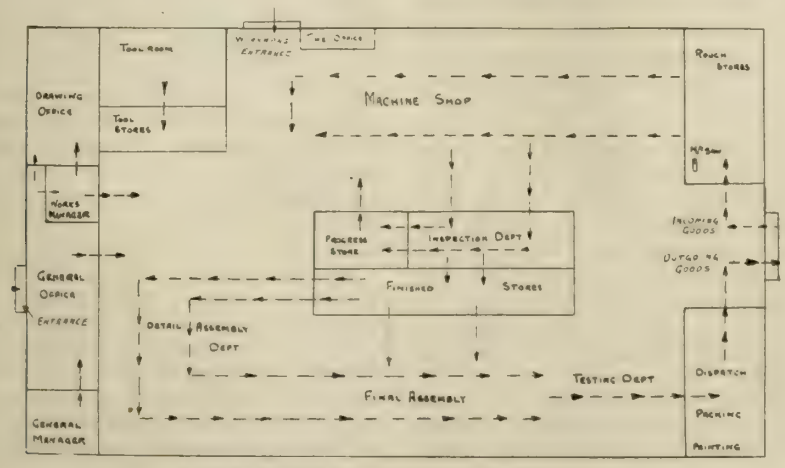
By G. BLAKE.

WHILE most engineering works (large and medium size) are laid out for systematic production, it is often the case that in the small shop the layout of the plant, stores, (inspection department, if there is one) does not get the attention it should, probably on account of the expense involved in re-organization and the lack of appreciation of the advantages to be derived from a re-arrangement. The author proposes to deal with the shop with a payroll of say between 50 and 100, and assuming that some speciality is being turned out, taking for example the manufacture of small power driven type pumps for automobiles, usually driven by gearing from the gear box.

Routing of Work

In most large shops it is so arranged that the raw material comes in at one end of the works and goes out at the other end finished, the work always travelling in one direction, this is of course the ideal condition, and while it is generally in evidence in the larger shops, it is seldom or ever encountered in the small ones, as generally the latter is built in or surrounded by other buildings, etc., so that there is little possibility of there being separate goods entrances and exits. The sketch shows the general layout of the small shop engaged on the manufacture of the type pumps as already mentioned, and it will be noted that there is a combined goods entrance and exit. When entering the shop from the goods entrance, the rough material store is on the right. A machine hack saw is placed inside the stores for cutting up all bar material, this saves a great deal of time, as in some shops the hack saw is placed in the machine shop, thus involving extra labor carrying or wheeling the material to the saw and back again to the stores to be issued to the machine shop or assembly department as required.

The storekeeper takes charge of all incoming and out-going goods, but in connection with the inspection of all incoming goods and materials, the inspector would be responsible.



Sequence of Operations

The direction of the flow of work is indicated by the dotted lines and arrow heads, it will be noted that the work after being issued by the stores, goes to the machine shop and from there to the inspection department, but most of the small details are inspected in the machine shop as they come from the machines, it being so arranged that by having an inspector patrolling the machine shop, gauging the work on site, a deal of handling and time can be saved. Another point is that the floor inspector can prevent in a great measure the accumulation of defective or spoiled work, as he can at once notify the charge hand and have the machine put right. The work after being gauged in this manner can be simply transferred to another machine for the next operation without having to go to the progress store.

When an operation, on a batch of work, has been completed the inspector would put a small tag on the work and on this tag would be shown the quantity machined, the operation, the operator's number, the date, together with the inspector's O. K. and initials. It would also show the next operation so that the parts could be taken right away to the machine for the following operation. Of course, where it was necessary to inspect the work on the surface table, it would be transferred to the inspection department, accompanied by the work ticket which is somewhat similar to the inspection tag, the work would then be inspected and, if correct, transferred to the progress store, adjoining and communicating with the inspection department, awaiting re-issue to the machine shop. The inspector's tag would again be used to denote the next operation.

The writer's intention is not to illustrate the various tags, tickets, or cards used in connection with the work, but to indicate the lines generally upon which all unnecessary handling of the work can be cut out, thereby increasing the productive capacity of the shop. It will be noted that the finished part stores adjoins and communicates with the inspection department, the other side and ends face the fitting and assembly department. The dotted lines and arrow heads here again indicate the flow of work, so that after passing the final inspection the parts are transferred to the finished stores, to be issued to the fitters and assemblers when required. Following the dotted lines and arrow heads, it will again be noted that the materials now made up into detail assemblies, are following in the one direction towards final assembly, testing, and thence to the painting, packing and despatch department, which is opposite to the rough material stores. The finished goods have now arrived at practically the same position as when brought in as raw material. The goods again at this point come under the control of the storekeeper who is responsible for the packing and despatch.

A word now about the tool room and tool store; these two departments adjoin and communicate with each other. Again referring to the sketch, it will be seen that the tool room is placed at one end of the machine shop. As most of the tool room's products are in connection with the machine shop, it is therefore in the best possible position; the tool store by being attached to the tool room, provides the necessary link in the chain (as it were) as the tool store attendant can have all jigs, tools, gauges, etc., tested and corrected when required, with the minimum amount of handling. The position of the tool store is conveniently placed for machine shop inspection and assembly departments The "tool room foreman" should have charge of the "tool store." By this arrangement the upkeep of jigs, tools, gauges, etc., would receive the proper amount of attention, as the tool room foreman would in this case be responsible.

Layout of small shop to promote efficiency.

The general manager's office communicates with the general office, which, in turn communicates with the works manager's office and drawing office. The works manager's office is in direct communication with the works and also the drawing office, the floor level of all the offices being about 2 feet higher than the floor level of the works, by this means the works manager can have a good view of practically the whole of the shop from his office window. Regarding the procedure adopted when an order is issued, first of all the sanction is given by the general manager or managing director, as the case happens, for the manufacture of say 10,000 tyre pumps, the order is made out in the general office and signed by the managing director, instructing the works manager to proceed with the manufacture of the specified quantity.

Purchasing Department

In large and medium sized works there is generally a buying department and the individual in charge is responsible for the ordering and purchasing of all materials, etc. This duty in the small shops falls on the works manager. The first thing the works manager sees to is the materials in stock in the rough stores. Supposing that there are enough materials to make 1,000 sets to commence on right away, he would issue a works order to all the foremen or charge hands in the works. All these orders are in varying colors, each color representing a department; one order is sent to the storekeeper, another to the tool room foreman, another to the machine shop foreman, another to the inspector, and one to the assembly department foreman. After this is done the works manager would get quotations for the supply of materials sufficient to complete the order, with enough to replace the material taken from stock, as it is policy to always have in hand sufficient material so that small rush orders may be dealt with promptly. The tool room foreman immediately on receipt of the order would see that all jigs, fixtures, tools, gauges, etc., were in readiness to be issued to the machine shop when required. The progress clerk, who is responsible to the works manager would have the making out of the orders to the various departments, and his next duty would be to see that the stores delivered the requisite material to the machine shop to commence the production of the pumps.

Progress System

There are many other details in connection with the small shop, for instance a progress system would be necessary so that production could be recorded, and again some form of payment by results would also be essential, but to specify any particular method or methods is not the author's intention. For example, what may suit one shop, may not be at all practicable in another, as it depends in a measure on the products of the firm. There is one point in passing, however, which may be mentioned, a manufacturing system if adopted must be adhered to. Its ultimate success does not so much depend on the individual who introduces it, as it does on the whole-hearted co-operation of all in the works, from the shop boy to works manager and even managing director. Some workmen are opposed to any new idea and it is those who are the brake on the wheels of advancement; foremen are not exempt either in this respect, as the author has not infrequently noted that they do not take kindly to the new introduction, consequently they do not concentrate on getting the system going properly. There is nothing so detrimental to a new scheme as lack of interest, or unwillingness on the part of an executive. Getting the foremen and charge hands to take up the new scheme in an enthusiastic manner and to insist on it being carried out, goes a long way towards its ultimate success.

THE USE AND ABUSE OF A VISE

Probably there is no tool in the shop which is subjected to so much unintelligent use as a vise. Most machine tools are put exclusively into the hands of trained men whose education and experience have taught them to know the strength of materials and to closely estimate the strain which may be safely put upon a piece of machinery; and, furthermore, not to exceed that strain unless the exigencies of the occasion demand it, in which case the possibly resulting breakage may be pardonable on the ground of temporary necessity. But a vise is generally at the service of any one who may temporarily have use for it. It has no protection against use which may be so devoid of intelligence as to constitute gross abuse. Unfortunately its functions and design are such as to provide within itself the means for its own destruction, and it is frequently forced into service for which it was not designed or intended. Oftentimes we see it used as a screwpress, which use is quite legitimate so long as the operator is one who knows the maximum pressure it can safely withstand, and who doesn't allow that pressure to be exceeded. But in the hands of the average helper or laborer, such use is generally disastrous. When he reaches the limit of pressure which can be exerted by the lever with which the screw is provided, a piece of gas pipe slipped onto the lever provides the convenient means by which the leverage may be increased almost indefinitely, and a break is pretty likely to follow. One very provoking outcome, if the perpetrator happens to be unobserved, is his releasing the pressure when he feels the vise "give," and thus knows that a fracture has been started, taking his work somewhere else and leaving his damage to be uncovered by the next user of the tool, who truthfully reports that the vise broke under very little strain. Another fruitful cause of breakage is the clamping near one end of a long piece of work which may thus have considerable overhang. Many times the operator, instead of hunting up a stick or other support to keep the free end from dropping, will attempt to hold it by excessive pressure between the vise jaws; and if in that condition the operation may involve any considerable hammering, the service exacted of that vise is most severe. One cause of a minor breakage is the clamping of a hard piece of metal so that the pressure is concentrated upon a small area near the margins or corners of the hardened jaw face; and if the jaw is hardened enough to resist battering or indentation, a piece is almost sure to be broken out, leaving an unsightly notch.

A very common fault with vise users is the failure to keep the screw lubricated. We have seen many vise nuts in which the thread had practically disappeared. The front jaw should be occasionally detached from the vise, turned over, and the screw lubricated its entire working length. When this is done at reasonable intervals, the screw and nut will wear indefinitely.

The use of vises having smooth faces for their gripping jaws is not nearly as extensive as it would be with a better comprehension of their capabilities. For most operations involving filing or light chipping only, smooth jaws will hold the work securely enough, and the necessity for using loose pieces of smooth metal between the jaws to prevent marring finished surfaces is obviated.

Treat your vises as you would treat any good tool in your shop, and your expense for replacements will be negligible.

From Prentiss booklet.

SPEED OF COMMUTATOR

The peripheral speed of a commutator or slip ring is the speed at which its surface is moving under the brush contact. It may be calculated by multiplying the diameter of the commutator or ring in feet by 3.1416 and by the number of revolutions per minute. Brush manufacturers rate their brushes for the maximum peripheral speed to which they are adapted. This rating applies to direct-current types of machines of average design, and may be increased from 20 to 50% for slip-ring service. Permissible peripheral speed is determined largely by the coefficient of friction of the brush, but there are other factors having an influence, and for this reason, says "Power," it is advisable to base the selection of a brush on the manufacturer's rating for permissible peripheral speed rather than on the coefficient of fiction.

A crane driven by a three-phase wound-rotor motor will handle loads quite as sensitively as a direct-current motor, but the latter is capable of performing more work in a given period, due to its higher speed of hoisting light loads and lowering, although the speed of hoisting maximum loads is the same for both types of cranes.

Vertical Turret Lathe as a Production Tool

Intensifying Actual Machining Time—Reducing Tool Setting Periods—Advantages of Multi-Cutting Process—Great Saving Effected in Machining Piston Heads

By E. P. BLANCHARD.

IN the development of machine tools for greater production at lower cost, it has been possible at times to combine the salient features of several types of machines into one unit, thus not only consolidating the gains in each type, but producing a machine of wider range, increased adaptability, and more economical operation. Materials are improved to meet the new conditions, control is studied for the convenience of operation and production proceeds on an advanced scale. The vertical turret lathe represents in combination an advanced development of the engine lathe, the horizontal turret lathe, and the vertical boring and turning mill. There are, of course, some conditions that are satisfactorily covered by the original types but the mass of work in this field is appreciably benefited by the machine here shown, a fact conveniently demonstrable.

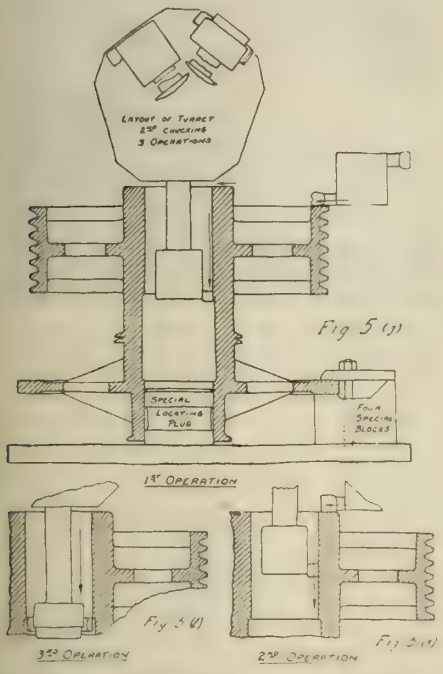


Fig. 5.—Sub-operations (j), (k), and (l).

Based on the proposition that all time is either used or not used for production, and that actual cutting time only, is productive, the problem with any machine is first to reduce the non-productive time with a corresponding increase in the productive, and second, to intensify the use of time in operation. The reduction of time between cuts is accomplished by convenience of control, elimination of unnecessary movement, and direct aid to the necessary. The use of productive time is intensified by the number of cuts that can be taken at once with proper feed and speed, the limiting factor in each being the ability of the cutting tool to stand up under these requirements.

The vertical turret lathe is an apt illustration of these principles, the inherent qualities being obvious in a study of its use. The performance of a battery of these machines at the Dayton Steel Foundry Co., demonstrated their ability to stand up to heavy work and places the responsibility of limiting production not on the machines but on the efficiency of cutting metal. Each machine was installed for a production of 18 truck wheels per day from cast manganese steel. The operations were rough turning, boring, facing and finishing. With tool steel, a speed of 40 feet per minute was used for roughing, and 65 feet per minute for finishing. By a change in cutting metal a roughing speed of 90 feet per minute and a finishing speed of 150 feet per minute was obtained. Production was doubled to 36 wheels per day from the same machines. The extra strain was not noticeable on the machines. A close up view of the tooling and the truck wheel chucked in the machine is shown in Fig. 2.

A complete study of the operations in the machining of a 26-inch diameter split gear of forged steel, Fig. 3, affords excellent opportunity of observing the machine under heavy work and clearly shows the value of turret tooling and multi-cutting. Line drawings of the piece and the tool layout are shown in Fig. 4. The successive operations are listed in the table showing clock times,

speed, feed and duration of each operation.

An analysis of the operations required in machining any given piece will indicate that with speeds and feeds equivalent to the capacity of the tool bits, or requirements of the work, the total cutting time per tool for any piece, will be the same regardless of the type of machine on which the work is done. On any machine, therefore, which is capable of work beyond the economical endurance of cutting metal, efforts for higher efficiency must be toward a reduction of non-productive time and a multiplied use of productive time. Such multi-cutting is the result of group tooling on one head, or of two heads cutting at once, or a combination of both methods.

The ability of a machine tool to thus concentrate extended single tool time into shorter simultaneous operation might be called "Simultation." Simultation varies with the requirements of the work in speed and feed, the adaptability of the machine, and the ingenuity of the operator. It might be expressed in the ratio of extended single tool time of 100 per cent. capacity to the actual operating time under simultaneous cutting.

Any machine tool capable of cutting continuously with a single tool at full capacity would finish a certain steam piston head in 116 minutes, plus such time as would be required to adjust that tool and make the changes in feed and speed. The vertical turret lathe furnishes the necessary power and rigid tool support for group tooling on each of two heads, and uses these heads simultaneously. Group tools are held in the turret and side head for successive operations, eliminating idle time between cuts. Control of all functions is centralized for further time saving and convenience of the operator. This is why the vertical turret lathe can reduce the extended single tool time for this piece to 48 minutes of intensive concentrated production, without straining the machine or the operator.

The vertical turret lathe can, by simultaneous cutting on several surfaces, give 60 minutes, 120 minutes, even 240 minutes of actual single tool productive

New Fibrous Material for Gear Construction

Water, Oil and Grease Proof—Tensile Strength Over 8,000 Pounds per Square Inch—Gears of Small Diameter Need no Shrouding—Insoluble and Infusible

THE MATERIAL is practically water, oil and grease proof. Ordinary solvents, alcohol, acetone, benzine, etc., do not affect it, and most acids and weak alkalaine solutions do not influence it in any way." These, and the following claims and uses are issued by the Diamond State Fibre Co., Toronto, who manufacture a non metallic gear cutting material known as "Condensite Celoron."

It is rodent proof, will not absorb moisture from the atmosphere, and will not deteriorate with age. It is highly resilient and amply able to withstand the sudden shocks and jars to which gears and pinions are often subjected. It is self-supporting. Gears and pinions cut to standard sizes require no shrouds or end plates. Only in extreme cases where the diameter and face are out of all proportions, or the stress at the key way is excessive, are end plates used, and then their function is usually one of reinforcement at the bore. Meshing end plates are never necessary. So far as their efficiency is concerned, gears made of this material require but two simple principles of common sense in their installation:

1.—They should never be meshed with gears of similar material or with gears having uncut or badly worn teeth.

2.—The face of the mating cut metal gear should always be equal to or wider than the condensate celoron gear. Grade F, the basic material from which these gears are made, may be described as a vulcanized woven fibre thoroughly impregnated with condensate and then hardened. This is a condensation product made of a combination of phenol and formaldehyde. When combined with fibre and hardened, it becomes extremely water-resistant, high in dielectric strength, and to all practical purposes is chemically inert, insoluble and infusible.

In general appearances it is smooth, hard, may be subjected to every machining process, and is suited to the cutting of silent gear and pinions. It is regularly supplied in standard sheets 36 in. by 36 in. and 36 in. by 40 in., and in standard thickness and from 1-32 in. to 3 in. inclusive.

To give an adequate idea of the physical properties, the following data has been prepared. Tests show that the material has a tensile strength of 8,000 to 10,000 pounds per square inch. Its compressive strength is approximately 40,000 pounds per square inch, laminae horizontal, and 2,500 pounds per square inch laminae vertical. The transverse strength is approximately 23,000 pounds per square inch, laminae horizontal; and 25,000 pounds per square inch, laminae vertical. Modulus of elasticity (the load per square inch divided by the elongation per inch) is approximately 1,550,000 pounds on the average of 10 readings. Specific gravity 1.3 to 1.4.

Brinnell hardness (by applying standard formula to the measurement of the impression made by a 10 mm. steel ball held under pressure of 500 kg. for 15 seconds) on natural face 45, on sawed face 36.40. Coefficient of expansion .000017 per degree Fahr. With absorption, test pieces 1 in. thick, .46 in 24 hours, 1.08 in one week. Absorption measured in percentage of original weight. The tests given are the average of many in order that any user may compute the factor of safety with greater security.

Standard Construction

The maximum thickness of a single sheet is three inches. In making gears up to a three-inch face certain standards of practice obtain, viz: The diameter of the whole depth circle must not be less than two times the diameter of the shaft. The distance from the root of the tooth to the key way should not be less than one and one-half times the height of the tooth.

For gears over three-inch face, the practice is to use two or more pieces fastened together. In this case the outside blank should not be less than one inch thick. Riveting is done under pressure. Where rivets are impractical, bolts may be used. If machine bolts are used countersink one outside blank to accommodate the head of the screw and tap the opposite blank to take the thread. Under a steady load, one way rotation, the maximum fibre stress on the key way may be safely estimated at 3,000 pounds per square inch. This figure, of course, where conditions are bad, and reversing service is necessary, must be reduced accordingly. In extreme cases the use of a larger key may help or end plates may be necessary.

On standard gears the use of shrouds is not recommended. Gears of large diameter in proportion to their face may, because of high pressure on the key way, require end plates or metal hub to relieve fibre stress. Gears of small diameter and larger bore may require end plates to prevent distortion when the key is driven. Extra hub strength may be necessary for a number of good reasons, but the usual duty of end plates is merely to preserve rigidity and good alignment.

Data on End Plates

Where end plates are used they should be steel, although for small gears brass may be used to advantage. Their outside diameter should be just a reasonable allowance over the rivet circle. They should never extend beyond the root of the tooth. Thickness should be as follows: up to 2 in., ⅛ in. dia.; from 3½ in. to 8 in., ¼ in. dia.; from 8 in. to 10 in., 5-16 in. dia.; from 10 in. and above, ⅜ in. dia.

In this type of construction the usual method is to mount a condensite celoron ring over the metal spider and fasten with rivets. To treat any gear right is to lengthen its life. A good trade of heavy graphite grease is recommended for gears of this material.

AN ENGINEERING MYSTERY

It seems impossible that an iron bar with a hole through the centre should be stronger than a solid bar of the same diameter, but this has actually been proved to be the case. A British firm has developed a very ingenious process of making what it calls a hollow cored bar with this increase of strength. The hollow core is really a small hole which extends from end to end of the bar. Obviously it would be a very costly business to bore a hole through the bar, and in consequence this firm has developed a clever way of making the bar hollow without drilling. The mass of metal from which the bar is drawn is drilled in the first case, and the hole is packed tight with a special composition. The ends of the hole are subsequently sealed by a patented process of welding. When the piece of metal is rolled in the mill into a long bar the packing stretches with the metal and preserves the continuity of the hole. One of the most important applications of this hollow cored bar is for mining drills where the hole is used for a current of air or a jet of water to cool the cutting edge. Where water is used it converts the dust made by the tool into slush before it can rise and be breathed by the miner. Thanks to this invention it is probable that the liability of miners to tuberculosis trouble will be greatly minimized. Hollow cored bars are also being used for a great variety of purposes in motor car construction and elsewhere. Arrangements have recently been made for the production of these hollow bars on a much larger scale than formerly.

All hoisting chains subjected to heavy stresses should be carefully inspected from time to time, for any signs of deficiency.

Never allow an emery wheel to vibrate when running at normal speed. If there is vibration, true up the wheel or re-babbitt the bearings after trueing up the journals.

Value of Experimental Work in Machine Building

Determining the Best Materials to Use for Various Purposes—Special Apparatus Provides Effective Test—Over 100,000 Reversals Made on Clutch in a Few Hours

THE EXPERIMENTAL department of the Alfred Herbert Co., has been of the greatest value in determining the best materials to use for various parts of machines and the best allowances for the various fits.

By the use of suitable experimental apparatus they have been able in many cases to give a machine, in a few hours, a test which would be equivalent to many years' working under ordinary conditions, and have thus been able to arrive at conclusions very much more quickly than by the ordinary method of trying machines out in the customers' works. The result is that in some cases constructions which might be criticised by casual observers are retained in use because exhaustive experimental tests have definitely proved them to be satisfactory.

Test on Clutches

An example of a test of this kind is shown in the accompanying illustration, showing a test which was made on the forward and reversing clutches of the 6½-in. single pulley head as fitted to the No. 4 Capstan Lathe and N. 1 Patent Hexagon Turret Lathe. In the early days of single pulley heads trouble was experienced with friction clutches, partly owing to the material from which they were made, partly owing to the methods of machining and the allowances for fit and wear.

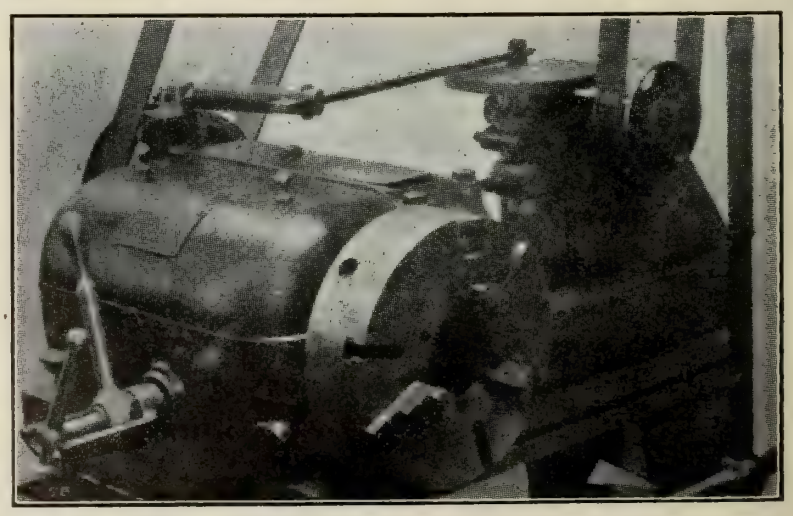
The tests in question were made with clutches of various materials, and the particulars given refer to one series of tests showing a clutch which proved satisfactory in use. As will be seen from the illustration, a special reversing lever was fitted to the headstock and was connected to a simple worm-driven crank motion rigged up for the purpose and driven by a pulley from overhead so as to reverse the spindle 18 times per minute. In order to thoroughly test the reverse a very heavy pattern chuck was fitted to the spindle, the weight of the chuck being 105-lbs. and the momentum such as to severely stress the friction clutch at the moment of reversal.

At the beginning of the tests the chuck speed was 224 r. p. m., and it was noted that after 1,620 reversals the clutches became very hot but caused no trouble. After 3,683 reversals the reverse clutch was adjusted and the head re-started, the chuck speed being raised to 334 r. p. m., which was continued throughout the entire tests. At 6 reversals the forward clutch was adjusted. At 10,163 reversals the reverse clutch was again adjusted. At 12,323 reversals the clutches were taken apart and examined; it was found that the friction rings and shells showed no appreciable signs of wear except at the corners of the rings, where slight wear was evident due to lack of roundness when sprung open. The clutch parts showed some signs of over-heating, so the speed of reversal was reduced to 8 reversals per minute, the chuck speed being as before, 334 r. p. m.

At 47,483 reversals the forward and reverse clutches were adjusted and the head taken to pieces for examination and cleaned out. The clutches were in good condition, and the grinding marks in both rings and shells were still visible. At 57,923 reversals the forward and reverse clutches were adjusted. The machine was then run until the number of reversals reached 101,603, which was considered sufficient, and the test was terminated.

Results of Test

On inspection of the clutches they were still found to be in excellent condition, the only wear in the rings being near the corners where expansion is at a maximum, and grinding marks were still visible in both friction rings and shells. During the whole of the tests the forward clutch was adjusted five times and the reverse clutch six times. The head was reversed 43,680 times after the last adjustment of the clutches, there being no further need for adjustment, and the clutches were in good condition at the end of the tests.



The above tests represented one stage in the progress of the friction clutches in question, further improvements having been made later on and additional tests of a similar character carried out.

The conditions under which these experiments were made were much more severe than anything which could take place in practice, as reversal of these heads in practice is only an occasional operation, and the heating effect caused by the constant reversal at high speed with a heavy chuck on the spindle would never take place in ordinary practice.

The knowledge that experiments of this kind give us is of the greatest value in ensuring that our machines shall work in a satisfactory manner after leaving the plant, and results in something of value in the machine which cannot be represented by catalogue particulars, but only by the reputation of the maker founded upon the performance of the machines in the works of the user.

CARBON TOOL STEEL STILL DESIRABLE

In these days when high-speed tool steel is being used by some people almost indiscriminately for all sorts of purposes, it is worth while remembering that carbon tool steels are still quite efficient when used with discretion. If users of tool steel will study the uses for which carbon steels can be relied upon, they will not use dearer steel than a given tool requires, and will thus be able to afford not to make other tools of poorer steel than will result in a perfect job. Economy in tool-making is very largely a question of choosing the right steel for every tool. The rules laid down by Messrs. Edgar Allen and Co., Limited, in their free pamphlet, "Carbon Tool Steels," cannot be applied blindly to every steel that the market offers; but they are right for each of the four classes, and six degrees of hardness in each class, which the "£.s.d." series provides. It is safe to say that if the rules laid down in this pamphlet as to the choice and the treatment of "£. s.d." carbon steels are followed, no tool maker need fear competition.

Experimental testing of friction clutch.

Mechanical Technology of Forge Shop Practice

Interest Shown by Manufacturers in Technical Training of Youth —Art of Welding and Working Iron—Model Forge Shop Lay-out—General Practice Exemplified

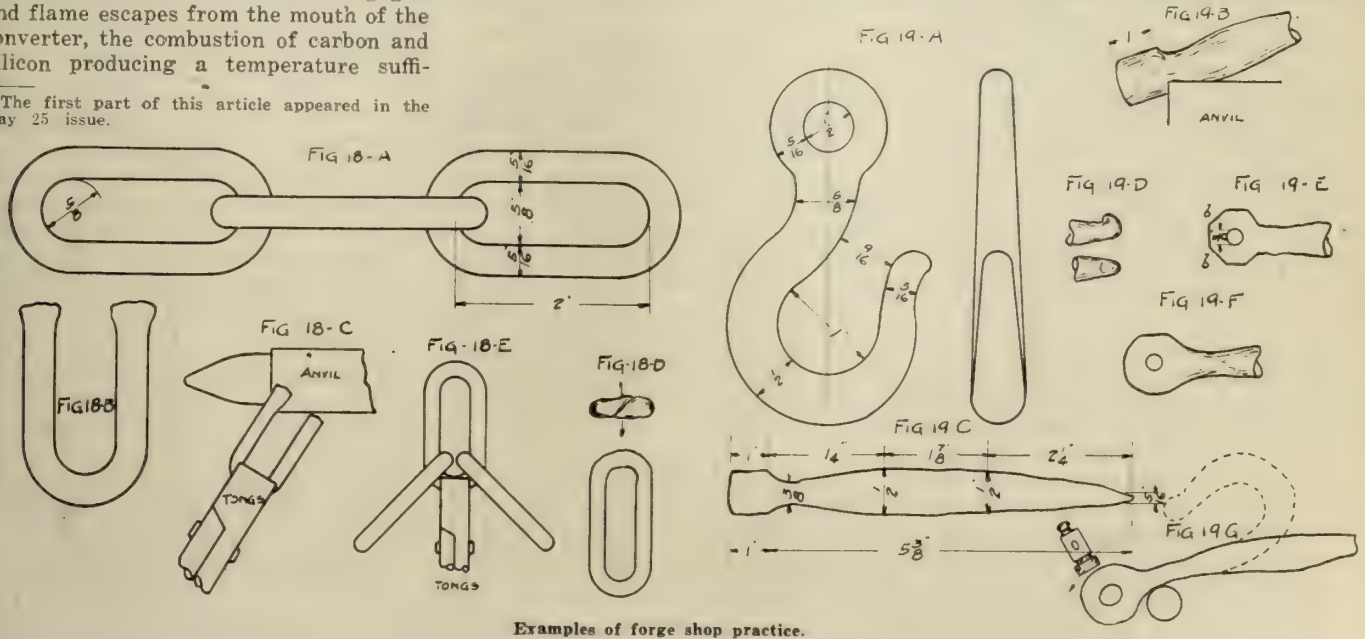
THE OPEN hearth method of making steel was discovered about the year 1845. It is under better control than the Bessemer process since at any time it affords opportunity for testing and for making such additions as may be necessary to yield the desired product. The open hearth furnace also permits of the highest temperature without requiring a strong draft. These furnaces are built to hold from ten to fifty tons of metal. The time for an operation or "heat" is from eight to eleven hours. Steel rails, structural materials, plates, etc., are produced by this process.

Bessemer Steel

The Bessemer process is named after its inventor, Sir Henry Bessemer, an Englishman, and was introduced in 1856. For many years after its introduction it ranked first among all the processes. Bessemer steel is made by decarbonizing cast-iron by forcing a current of air through the molten metal in a pear-shaped crucible or vessel called a "converter." There has been little change in the design of the converter from that originally used. A common size of this converter has the following dimensions: Diameter 8 ft., height 15 ft. It is made of boiler plate, lined with refractory material. It is suspended upon an axis to admit of its being turned from an upright to a horizontal position. In the bottom there are twelve tuyeres, which have to be replaced after about twelve or fifteen blows or heats. The usual capacity of the converter is from six to fifteen tons of cast-iron. The blast of air forced through the molten cast-iron, produces great heat. The resulting gas and flame escapes from the mouth of the converter, the combustion of carbon and silicon producing a temperature sufficient to keep the mass thoroughly melted, thus quickly burning out the carbon and silicon, this last result being indicated by the color of the flame. The molten metal is poured into a ladle and then there is added to it, manganiferous pig-iron, which reintroduces the necessary amount of carbon and manganese. This entire process takes about twenty minutes. It is then cast into ingots, and, after being treated in the reheating furnace or "soaking-pit" is rolled to the required thickness. Bessemer steel is used for nails, screws, wire, and in fact, for all products where cheapness rather than quality is the requirement.

Crucible Steel

Crucible or tool steel, the oldest and simplest process, takes its name from the methods employed in its manufacture. In this process, carbon is added to a low phosphorus and sulphur wrought iron. Swedish or Norway iron is used in preference to other kinds, as it has proved superior in making high grade tool steel. The iron is cut into small pieces one inch long from flat iron bars 2" x ½". These pieces are then placed in a clay crucible (sometimes a graphite crucible is used, although it is not as good) which is about 20" high and 1 foot in diameter. A certain amount of powdered charcoal is mixed with these pieces and the crucible is then tightly sealed, and subjected to great heat which melts the iron. After having remained in a molten state for some time, it is poured into molds and form-ingots which are afterwards rolled or hammered under a steam hammer into bars. This process has undergone but little change in all the years it has been employed, the only important change being a more direct method for introducing the carbon into the steel. In the main, however, the method now used is the same as that used centuries ago. Owing to the high cost of production this method is now used principally for making high grade tool steel. The elasticity of this steel, makes it of use in many places where no other steel could be safely used.



Tempering

The term "temper" as used by steel makers, refers to the percentage of carbon in the steel. It has a different meaning when used by the steel maker than when used by the hardener. In the steel mill, it means the amount of carbon the steel contains. According to "Metcalf" the meanings may be tabulated as follows:

Very high temper .....carbon 150
High temper ..... carbon 100 to 120
Medium temper ..... carbon 70 to 80
Mild temper ..... carbon 40 to 60
Low temper ..... carbon 20 to 30
Soft or dead soft temper, carbon 20

A point is 1/100 of 1% of any element that enters into the composition of steel, so: a 150 point carbon steel, contains 1½% carbon. In the steel mill such a steel is spoken of as 150 steel. "Tempering" on the other hand, denotes the process by which steel is brought to a previously determined degree of hardness. A steel chisel can be made so hard that it will cut another piece of steel; or so soft that driving it into a piece of hard wood will dull its point. This property of steel enables the mechanic to make it into tools suitable for

The first part of this article appeared in the May 25 issue.

Examples of forge shop practice.

any kind of work. Steel is tempered by various means, all of which depend upon a heating and subsequent cooling of the metal. For instance, a piece of tool steel which is heated to a cherry red heat and then plunged into cold water, becomes very hard. If allowed to cool slowly, it becomes soft. Between these extremes all degrees of hardness can be obtained. Every tool is tempered to the hardness that makes it most useful. When a polished piece of steel, hardened or unhardened, is exposed to heat in the presence of air, it assumes different colors as the heat increases. First will be noted a faint straw color, which changes to a deeper straw, then to a dark brown with purple spots, then to a dark blue, and finally to a light blue. These colors are due to a thin film of oxide that forms as the heat progresses. These colors are valueless, however, to the tool maker unless the metal has first been cooled in a bath of water, oil, or some other liquid, when at red heat. Drawing hardened steel to any of these colors is called "tempering." The following list of colors applies to all of the tools we are likely to make:

Color

Pale or light straw, lathe tools; dark straw, taps, dies, milling cutters, etc. Woodworking tools (cooled in oil); purple, center punch, stone drills; dark blue, cold or cape chisels; light blue, screw drivers.

Tool Tempering

Let us consider the tempering of a tool, taking, for example the cold chisel, a tool widely known and generally abused. To obtain a good chisel it must be properly forged at a comparatively low heat, and then hammered with light blows at the last until it has cooled considerably below the heat ordinarily used when metal is displaced. The object of the light blow on the cooling metal, is to close the grain or refine the steel, making it tough. Tools of this character stand up better if they are heated to a cherry red heat and allowed to cool before hardening. This is not always possible, but when it is, make the hardening heat a separate operation. To harden, heat two-thirds of the part forged to a cherry red heat, using great care not to overheat the point, and then cool one-half the blade in cold water; always move the tool about or set the water in motion, avoiding any danger of making a water crack at the water edge. The next operation is to brighten one broad surface with an emery stick. A piece of emery cloth tacked over a stick of wood makes a very good polisher. The heat remaining in the body of the chisel will reheat the end already cooled, and the various colors will appear in order on the polished surface. The proper color for a cold chisel when correctly tempered, is dark blue. When this color is attained at the point the entire tool is then immersed in water and is not removed until cold. If the tool is not cooled off enough in the first operation, the colors will run down very rapidly and become compact, and if not watched closely, they will be gone before the tool can be cooled. When a tool is to be hardened all over, it is first heated to a cherry red heat and then cooled. After brightening with the emery stick, place on a square or flat piece of hot iron. The tool will absorb the heat and the colors will soon commence to run. When the desired color is attained cool again in water or oil. In a commercial plant where a great many tools of the same kind are made, and where the composition of the steel is known, a hardening bath is used.

Spring Tempering

The method employed in hardening a spring in oil is as follows: First, heat to a cherry red heat, as in hardening in water; cool all over in oil; hold over the fire until the oil upon the surface blazes. This is called "flashing." Cool again in oil. This "flashing" is done three times before the process is complete. Another method of hardening a spring employs a water bath instead of the oil. Pass the spring over the fire or through a flame until it is hot enough to make a pine stick show sparks; then cool in water and a spring "temper" results.

Annealing

The process of softening a piece of steel is called "annealing." A piece of steel is softened or "annealed" prior to being worked upon in the lathe or otherwise machined, as this process brings about a uniform softening, relieving any strain that might have occurred in forging. To anneal a piece of steel it should first be heated to a cherry red heat, and then allowed to cool slowly. When long pieces of steel, or a number of pieces, are to be annealed and a furnace is employed, the pieces are placed in a long tube or pipe, and both ends sealed. They are then brought to a cherry red heat and allowed to cool. When a piece is heated in the forge, it is covered over in the annealing box.

Exercise No. 19

Stock—Norway Iron—⅜″ x 1″—4½″ long. The hook as shown by Fig. 19 A is the finished piece. Operation—Lay off center punch mark 1″ from one end. Heat and draw first to the form shown by Fig. 19 B, then to that shown by Fig. 19 C. Set over the end, Fig. 19 C, and finish as shown by Fig. 19 D. Cut the corners, punch the hole, Fig. 19 E, and draw the eye on the horn to the form shown by Fig. 19 E. Heat at O, Fig. 19 F, cool the eye and bend as shown by Fig. 19 G. Complete the bending as indicated by the dotted lines, Fig. 19 G.

Exercise No. 18

Stock—Norway Iron—3 pieces—5/16″ diameter—6″ long. Three links of a chain, shown in Fig. 18 A, form the finished piece. Operation—Upset each end of the piece, taking one heat for each end. Heat the piece in the center, cool about 1½″ of each end and bend to the shape of the letter U, Fig. 18 B. In scarfing the ends, place one end upon the sharp edge of the anvil, Fig. 18 C, and striking light blows, swing the piece around bringing the toe of the scarf to a thin edge. After one end is scarfed turn the piece over and scarf the other in the same manner. Bend the scarfed ends over the horn of the anvil so they will lap as shown by Fig. 18 D. Weld and finish two links each independent of the other and complete in itself. Bring third link to the form of Fig. 18 D. Spread the ends in the direction shown by arrows and slip on the finished links. Apply the tongs as shown in Fig. 18 E, close the ends of the link, and weld. In finishing see that the links are of the same size and form.

WHAT A MACHINIST SHOULD LEARN DURING HIS TRAINING

Lathe work: Grinding tools; centering; laying out; facing; straight turning; turning to shoulders; taper turning; combined straight and taper turning; turning precision work to micrometer, limit, ring and snap gauge; cutting V, U. S. S., U. S. F., Acme, Whitworth, Square, Buttress and Worm Threads; boring; facing; turning, recessing, threading, etc., in chuck; setting up work on face plate; eccentric crankshaft, and oval work; taper turning and boring, three cases; making running, sucking, wring, press, and shrink fits; use of hand tools and various attachments, such as grinding, relieving, etc.

Milling machine work: Milling surface on cast iron, steel, brass, etc., held in chuck clamped to platen, or held in jigs or fixtures, using vertical and vertical and horizontal feeds; use of spiral, helical, and straight cutters, and mills, butt mills, etc.; use of dividing head for cutting keyways, shapers, spur, bevel and worm gears; helical milling; fractional or degree spacing; simple, indirect, compound and differential indexing; making jigs and fixtures; precision work.

Grinding: Knowledge of grade and grain of wheels, and ability to make choice to suit conditions; method of mounting; truing and balancing; care of the machine, supporting the work; external and tapering roughing and finishing; taper, form and plane surface grinding; sharpening cutters, reamers, taps and dies.

Miscellaneous work: Rigging up to handle heavy work; methods of doing work too large for machines at disposal, making special appliances to do unusual jobs; emergency repairs; knots and splices in rope and cable; hanging shafting; fitting belts; various methods of lacing belts; setting up machinery.

Floor and heavy assembly: Lining up machinery; babbitting, scraping, and line reaming bearings; fitting bushings; assembling heavy parts; adjusting and timing cams, valves, and motions; trouble shooting; fitting and removing keys; grinding in heavy parts; use of portable tools, final testing and adjusting.

In addition, says this report of the Metal Trades Association, those being prepared for the precision divisions of the trade should be thoroughly taught to use all the instruments which are used, and have an extended knowledge of the button, disc, and datum bar methods, as well as any others that may be introduced commercially.

A Newly Developed Heat Resisting Alloy—Calite

Compound That is Strong Will Withstand Shocks, Can be Quenched Repeatedly, and is Highly Resistant to Oxidation—Metal Runs Freely—Shrinkage Same as Steel

By G. R. BROPHY

FRESHLY cut aluminum, like all metals, will show a bright lustrous surface, but after a very short time in the atmosphere becomes dull. On longer exposure little change takes place in this strongly adherent coating. This is recognized as a protective coating of oxide. Aluminum when alloyed in solid solution with other metals still retains this property of oxidizing and lends this property to the alloy.

Advantage of this property was taken a few years ago when calorizing was developed. This process, which has been described many times, consists of coating metals with aluminum at high temperature, actually forming a surface alloy which is highly resistant to oxidation at high temperature and to many forms of corrosion. Calorizing is not suited for work above 1,832 degrees Fahr., due to the rapid diffusion of aluminum and the consequent lowering of the surface aluminum content to the point where breakdown under oxidation occurs.

A homogeneous alloy made by melting aluminum with iron naturally will show no such diffusion on subsequent heating, and provided the aluminum content is sufficiently high, the alloy will resist oxidation at temperatures nearly up to its melting point. Unfortunately, on repeated heating and rapid cooling, or uneven heating, these alloys crack badly and no homeopathic doses of any third metal tried—and nearly all were tried—helped this condition. The hot metal when the least moisture touched it acted like hot glass, flying to pieces.

The low expansion of high nickel together with the fact that aluminum and nickel form a high melting compound led to investigating the promising ternary alloys of aluminum, nickel and iron. Therefore, keeping aluminum at a minimum and substituting nickel for iron in various percentages, a series of alloys was obtained which showed increasingly good properties. However, when nickel reached 15 per cent. the alloy was soft and lost nearly all its resistance to oxidation. This was probably due to the formation of a high melting compound corresponding to the formula Ni_3Al, which, while highly resistant to oxidation itself, robbed the iron of its protection and allowed the iron to scale badly. Further additions of aluminum and nickel in proportions other than that of the above compound finally gave an alloy which was strong; would stand shock, hot or cold; could be quenched repeatedly and was highly resistant to oxidation. A few further refinements gave the alloy which was finally adopted and which we will call calite.

Manganese and silicon above 0.75 per cent. both tend to decrease resistance to oxidation, but with care in melting, no trouble is experienced. Carbon increases brittleness and should be kept as low as possible and easily runs under 0.05 per cent. On account of the ease with which SiO_2 slags with aluminum, the melting must be done in a basic furnace. Also the ladle used must have a basic lining.

Basic Heroult type furnaces are used with good success. Steel scrap is first melted down and decarburized; slag is removed and nickel is added and a new slag made. When all is thoroughly deoxidized, the final slag is removed and scrap calite added to the extent of 25 per cent. of the melt and dissolved. The melt is then poured in a preheated ladle containing the required amount of molten aluminum. As this alloying takes place, an exothermic reaction occurs of sufficient intensity to dissolve additional scrap, and up to the present, scrap amounting to 15 per cent. of the melt has been dissolved with sufficient residual heat to necessitate holding in the ladle several minutes. The ladle is bottom poured so that the time of holding allows all oxide to float and nothing but clean metal to be poured.

The metal runs freely, and sections of 3/16-inch have been cast successfully. Any casting which can be made of steel can be made of calite. The shrinkage being the same as steel, the same precautions must be taken.

Calite resists oxidation up to 1,300 degrees Cent. (2,372 degrees Fahr.) but 1,200 degrees Cent. (2,200 degrees Fahr.) is recommended for indefinite service. The protective oxide formed is tight and does not snap off even on quenching from high temperatures. Quenching after 100 hours at 1,200 degrees Cent., calite lost but 0.03 gram per square centimeter exposed, while the best heat resisting base metal alloy other than calite lost 0.56 gram under the same conditions. The same samples were run at 1,300 degrees Cent. for an additional 25 hours. Calite lost 0.003 gram, the other 0.09 gram per square centimeter exposed. From these figures it appears that calite is 20 times as resistant at 1,200 degrees Cent. and the only base metal alloy to stand at temperatures higher. At 900 degrees Cent. or ordinary operating temperatures the loss per square centimeter was measured in 1/10 milligram, or for all practical purposes no loss.

Calite is practically non-corrosive. Samples have been polished and run in a spray of saturated sea salt solution at 100 degrees Fahr. for 200 hours and at the end of this time still retained the perfect polish. So called stainless steel will last but a few hours in this test. For fittings exposed to salt atmosphere calite should be excellent.

Twenty-five per cent. sulphuric acid dissolves calite rapidly; hydrochloric acid slowly and nitric hardly at all. Forty-eight hours in 25 per cent. nitric acid, the metal lost 0.0004 gram per square centimeter exposed. Acetic acid has no effect. Molten carbonates, chlorides, nitrates, cyanides, Ph, Zn, Sn, type metal, sulphur and sulphur vapor do not attack calite. SO_2 gas at 900 degrees Cent. has no attack. Fluxes such as cryolite, borates and silicates attack calite rapidly.

In general, the physical properties are as follows:

Melting point, degrees Fahr.	2,777
Softening temperatures, degrees Fahr.	2,500
Working temperature, degrees Fahr.	2,200 2370
Specific gravity	7.03
Weight per cubic inch, pounds	0.25
Brinell hardness, annealed	286
Scleroscope hardness, Annealed	40
Thermal conductivity, per cent. of iron	25
Transverse stress, 1-inch square bar, pounds per square inch	4,250
Tensile stress, pounds per square inch	36,800

Calite cannot be machined in the cast condition, nor cut with oxy-acetylene. Any change of dimension or finish must be done by grinding. It is more resistant to oxidation at high temperatures and will stand higher temperatures than any base metal alloy tested. Its first cost is low and operating cost lower than other non-oxidizing alloys. Boxes shown in the accompanying illustration have been run for 1,500 heat hours and will be seen to be in the best condition. Measurements of these boxes show no warpage or growth. The oxide coating is no heavier now than after the first heat.

The total value of building permits issued in the city of Oshawa for the month of May exceeds that for any previous month this year. Among the permits is one for a large industrial plant and many residences.

Practical Ideas From Practical Men

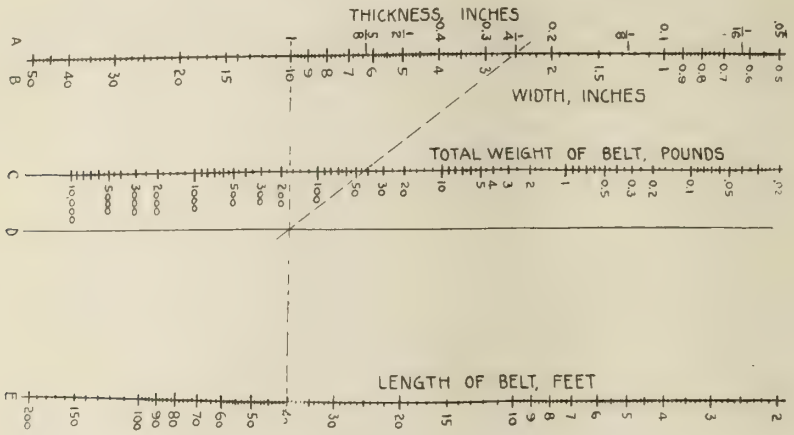
FRACTIONS AND DECIMALS

By W. F. Schaphorst

There is a difference between decimals and fractions, as everybody should know: .005 inch means 5/1,000 inch, and .0005 inch means 5/10,000 inch., or one half of one one-thousandth—a term that is very much used nowadays. Yet, there seems to be a tendency on foot to confuse the simplicity of decimals and make a deplorable combination of the two, like this: — .000½ inch. What does .000½ inch represent? A half of a thousandth or a half of a ten-thousandth? I don't know. Although those who write such expressions claim that it means a half thousandth, I rigidly maintain that it means nothing. There is no such animal. There is no excuse for balling our mathematics up in such a way as that and the habit should be stopped before too many catch it. If a half of one-thousandth inch is to be written it should be written in this way:

$$.0005 \text{ in.} = \frac{1}{2{,}000} \text{ in.}$$

$$\text{or} \quad \frac{1}{2} \times \frac{1 \text{ in.}}{2{,}000} = \frac{\text{or } 0.5 \text{ in.}}{1{,}000}$$



All of these are in perfect accord with mathematical practice and there is no question as to their meaning. Why use a questionable method?

FINDING LENGTH OF A LEATHER BELT BY WEIGHING

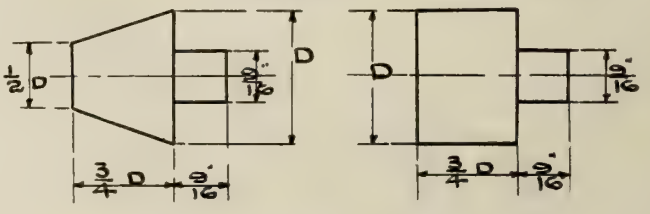
By W. E. S.

Put your belt on a pair of scales, get the correct weight, measure the thickness and width, and then lay the ruler across this chart twice and column E will tell the length in feet. The belt needn't be rolled up neatly; it can be a jumbled up mess, as belts sometimes are, yet the scales won't lie. There is nothing miraculous about this method. It is based on the fact that leather belting weighs 0.035 pounds per cubic inch. So, knowing the width and thickness one can solve "backwards" for the length. This chart, however, does away with the figuring. For example, what is the length of a belt whose thickness is ¼ in., whose weight is 42 pounds, and whose width is 10 inches?

Connect the ¼ (column A) with the intersect column D (as indicated by the dotted line) then run a line through that intersection and the 10 (Column B) and the intersection with column E gives

42 (column C) and extend the line to the answer as 40 feet.

When measuring the thickness of a belt it is well to use considerable care since a fractional part of an inch on this chart will make a great difference in the answer as you may readily observe. If the belt is rolled up, measure the total thickness of ten layers. It is then easy to divide by ten. For example if you find the total thickness of ten layers to be 2⅜ in. you know that to equal 2.375 in. Dividing by 10 the thickness of the belt is therefore 0.2375 in. You couldn't do much better with a pair of micrometer calipers. The range of this chart, it will be noted, is great enough to include all ordinary and many extraordinary belts.



STANDARD CORE PARTS

By Robert Mawson

The trend of the times in machine shop practice is to standardize the various elements used for the machines as far as possible. This practice has at least a two-fold advantage—the making of less varied elements and, as will naturally follow, the keeping for repair purposes more parts similar in design. We have recently followed the same idea in our pattern shop. It is a well known fact that if a number of patterns were made in the same shop even by the same man with an intervening length of time between them, the necessary though often considered unimportant core print would be of a different shape on the various patterns. This necessitates an excess of core boxes even for the same diameter of core which could be avoided by standardizing the core prints.

Referring to the illustration it will be seen that both taper and straight core prints are shown—to be used on the cope and drag sides of the patterns. The shank, which fits into the pattern is made of one size so that the pattern maker will not have to use different sizes of drills for various core prints—he gets used to one standard size—9/16 in. The length of the core print body is made to one ratio—namely ¾ of the diameter. I have given a list of the prints we carry in stock, but some of these could be conveniently dropped in many shops. The obvious advantage of these standard core prints is the reduction of core boxes required, only one being necessary for each diameter of core. The following of such a system will be found profitable to both the small and large machine shops or foundries.

STANDARD CORE PRINTS.

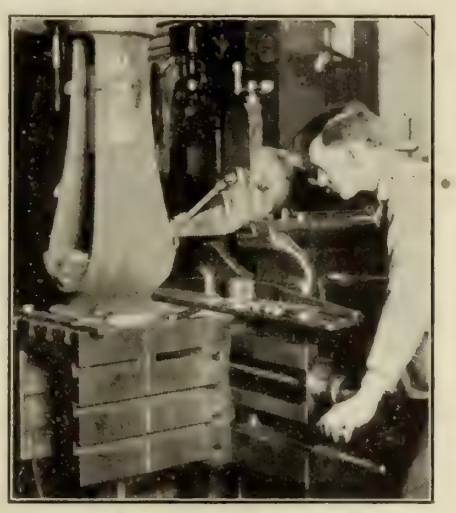
MACHINING A FORKED CONNECTING ROD



By H. Alton

A rather unusual set-up for machining the surface indicated at A in Fig. 1. was recently noticed in a Montreal shop. The part is a connecting rod for an engine which drives a pump forming part of

the auxiliary equipment in marine engine rooms. The surface is a segment of a circle and the operation was done on a shaper to which a special fixture was attached.

A diagram of the fixture, the method of attaching it to the shaper and the means of mounting and feeding the work is shown in Fig. 2. The connecting-rod is driven on an arbor B which is mounted in a frame. Spacers are placed between the ends of the forked rod as shown at C. Then the nut D is drawn up tightly. The frame of the fixture is bolted to an angle plate E which in turn is bolted to the shaper table as shown. On the inner end of the arbor, a worm wheel F is keyed and bolted. The worm G works into the worm wheel F. The worm is keyed to a small shaft on the end of which is a handwheel. The shaper tool is of the ordinary round nose type, carried in a standard tool holder. The ram works in the usual way and the cut is started at X as shown in Fig. 1. The rod is thus at the position shown in Fig. 3 at the commencement of the cutting. In order to obtain good cutting results and to overcome the fact that gravity permits the rod to move downward if there is any blacklash in the worm and worm gear, a weight is hung on the rod as shown in Fig. 3. This weight is sufficient to counteract the tendency of the tool to rotate the rod in a direction opposite to that which gravity tends, when cutting is actually taking place. When the weight is heavy enough the worm and worm gear feed the rod in much the same manner as it would, if the theoretical condition of no back-lash, existed. The worm just permits gravity through the combined weights of the rod and weight to advance a certain distance every time the worm is moved. Thus regular, even movements of the hand wheel produce as good results as can be obtained under any hand feed conditions. When the rod has passed that point where it is vertical and it commences to rise on the other side the weight is removed. Under the new conditions gravity holds the rod in a manner that the backlash is automatically taken care of.

The work is quickly and neatly done. By using a finishing tool with rather a flat cutting edge, but with the corners rounded to make fillets at the beginning and end of the cutting, a very satisfactory surface can be obtained. As the work is largely overhung an integral extension of the arbor is provided. This is shown in Fig. 3. The extension is supported by a rigid but adjustable floor stand. The cutting is accomplished with little of the objectionable spring and chatter.

UNUSUAL SHAPER JOB

By G. P. B.

Out-of-the-ordinary jobs are often performed on shapers, but here is a regular shop production job, being performed on a 24-inch Gould & Eberhardt shaper, that has proven itself to be much more economical from the viewpoint of handling the work, ease of setting up the job, and actual cutting time, than has been found possible by any other method. The operation consists in planing the bearing seats for the caps on 6 in. x 6 in. horizontal compressor frames, built by the Brunswick Refrigerator Co. at New Brunswick, New Jersey.

A special extension tool holder, with an over reach of 6 in. beyond the regular tool position, is used. It enables the tool to plane the entire length of the bearing which is 4⅝ in. long, without having the shaper head interfere with the compressor frame, since the sides of the frame are not far enough apart to permit the shaper head or ram to pass through. The two sides of one bearing are planed, then the casting is turned through a 180 degree position, bringing the opposite bearing in place to be planed. The high duty shaper with its ruggedly supported table, adapts itself very easily to such unusually heavy castings; also on account of the convenient size table which permits the operator to work on three sides for setting up the large heavy casting; and then, the rigid construction of the ram permits the taking of unusually heavy cuts in roughing operations; two vitally important factors to be considered in performing heavy work of this type. Previous to performing this operation on a shaper, it was done on a planer; but actual time studies prove that a saving of thirty per cent. in time for handling and setting-up the casting, also in machining costs, is being effected by the shaper method—a very noticeable saving indeed, considering the similarity of the operations on these two types of machine tools.

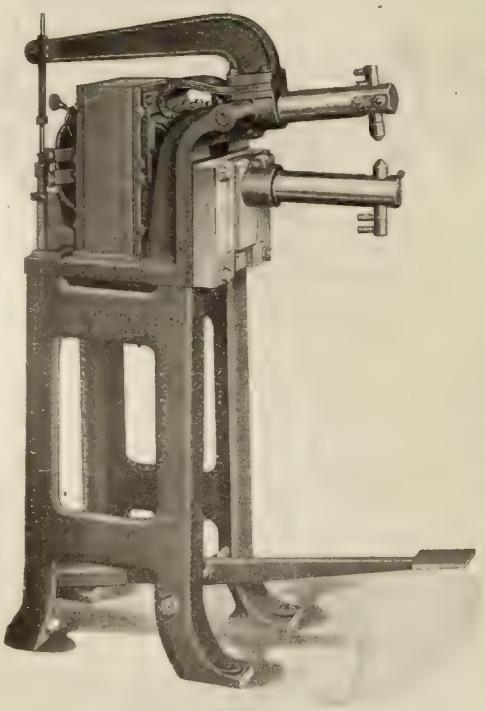
New Things in Shop Equipment

METAL PARTS WASHING MACHINE

An automatic metal parts washing machine which consists essentially of an endless belt conveyor combined with a washing apparatus has recently been placed on the market. As the work travels over the conveyor it passes through two sets of sprays which operate on both sides and on the top and bottom of the work. The fluid is circulated by means of a pump. All parts that can be handled by racks are put through the machine in that manner but larger castings may be placed directly on the conveyor. The machine is manufactured by the Colts Patent Firearms Manufacturing Co., of Hartford, Conn.

PORTABLE POWER HACK SAW



A portable power hack saw for cutting both machine and tool steel has recently been placed on the market. The saw is driven from a small motor direct connected through cut gears. The current is taken from any light socket. The cutting is done on the back stroke, the saw blade being automatically relieved on the forward stroke to reduce the wear and prolong the life of the blade. The feed is regulated by a weight that can be adjusted to suit the work. When the saw arm is raised to enable the work to be put in place, it is automatically held in position until released by the operator. The machine stops automatically when a cut is finished, and can be arranged to stop at any time during a cut. The machine is manufactured by the Edmund Machinery Co., of Cortland, N.Y.

TRIPLE COMBINATION PUNCHING AND SHEARING MACHINE

A combination punching and shearing machine that can be adapted to different types of work without the necessity of changing tools has recently been placed on the market. Every convenience is provided for the economic operation of the machine as the fly wheel and driving gears are placed on the opposite side to that of the operator. The knives of the plate shear are longer than in former models of this machine. Ample room is provided behind the knives to avoid any binding while the plates are being cut. Any of the standard structurals may be handled conveniently in this machine. The standard equipment with the machine provides for cutting rounds, squares, angles and tees only. The knives can be easily changed for cutting special shapes. The frame is made of cast steel and all pin bolts are provided to keep the covers of the slides from working loose. The machines are made in a number of sizes and are fully standardized and provision made for carrying cranes, gauges and other attachments, which can be furnished with the machine or supplied when needed. These machines are being offered to the trade by Amplex Incorporated, New York, N. Y.

SPOT WELDING MACHINE

A spot welder as shown in the illustration has been placed on the market recently. This machine will handle all classes of material up to two 10 gauge thicknesses. It can also be adapted to weld stock as thin as 26 or 28 gauge without difficulty, or 26 gauge can be successfully welded to 10 or 12 gauge material. This feature is obtained by a rheostat having five points which allows operator to stop the current up or down according to work being welded. The arms are adjustable, and the lower one can be raised or lowered as desired. They are 14 inches long, and the points at end of arms are both adjustable and interchangeable. Special point can be applied for welding angles, or for close welding in corners on such work as rectangular boxes, etc. Two models are made, 220V, and a magnetic switch is provided on both machines. All parts are of rugged construction, and the new tool has been officially passed by the Hydro. This concern also make welding machinery and intend developing other sizes of spot welders. These machines are manufactured by the Globe Engineering Co. of Hamilton, Ont.

Spot welding machine.

DEMOUNTABLE STEEL TRESTLE

A specially designed trestle for use in industrial plants, made entirely of steel, has recently been placed on the market. The supports are made in pyramid form. The top bar is provided with several notches at either end for adjusting the distance between the trestles. The demountable feature of the appliance provides for ready and swift assembly and likewise requires a small amount of space for storage. The heights vary from 13½ to 30in. and the weight ranges from 11 to 30 lbs. They are manufactured by Reinhold Bettermann, Johnstown, Pa.

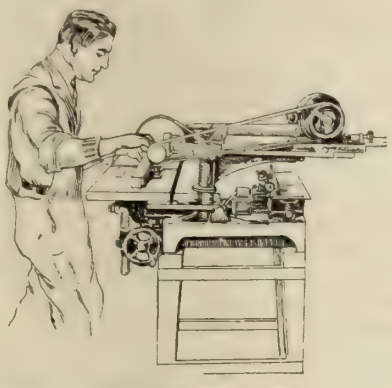
COMBINATION BENCH MACHINES

A combination tool intended for use in garages and service stations has recently been offered to the trade. It is equipped with various attachments, these being used for drilling wood or metal, for surfacing or sanding, disk grinding, polishing, buffing, tool grinding, or for rip sawing wood. The attachment can be fitted to the machine by removing the table. The table can be tilted if necessary for sawing at an angle. The frame, which may be attached to the bench, is made of cast iron and in one piece and the spindles are made of high-grade carbon steel. Connection is made between the horizontal and spindle by means of bevelled gears and is driven to a positive steel clutch. Bronze bearings are provided in both spindles. A Jacobs chuck is provided that takes drills up to ⅝ inch. The appliance is manufactured by the Ster-O-Lock Mfg. Co., Chicago, Ill.

PISTON-PIN BUSHING REAMER

A piston-pin bushing reamer has recently been placed on the market. The cutter of this tool is very similar to the regular reamer of the same make and is adjusted in the same manner. The shank and pilot stem are ground to an accurate sliding fit with a taper. The reamer is centralized and supported by means of a pilot stem passing through the piston-pin bushing. When short pins are used in pistons of small diameter it is sometimes necessary to ream first one bushing and then reverse the reamer and plug and ream the other bushing. There is no adjustment needed on the taper plug. There is a gradual adjustment on the plug but sufficient to cover the range of the reamer. Reamers are made in eight different sizes and are manufactured by the Alvord Reamer & Tool Co., Millersburg, Pa.

TWO-WAY BORING MACHINE



A very interesting machine that has been designed for boring simultaneously both sides of a piece of work, has recently been placed on the market. It is especially applicable for boring, bottoming, and reaming, both the exhaust and in ake ports of gas engine cylinders. The machine is motor driven and is semi-automatic in operation. The work holder to which the cylinder blocks are clamped accommodates four cylinders and is arranged to rotate about its central axis. The multiple heads at the two ends of the machine are fed towards the centre simultaneously where they finish the work and then return to their outer positions. Thus both sides of the cylinder are finished at the same setting. The work holder is then indexed to the next position and the feed for the heads again engaged and the cycle repeated. Loading and unloading the work is done while the machine is in operation. In fact the machine is capable of machining the castings as fast as the operator can feed it. The cycle of operations requires 20 seconds in which time one cylinder block is completely bored, reamed, and bottomed on two sides. Two holes 1-9/16in. in diam. and 1in. deep are held to 0.001in. limits in dia. and plus or minus 0.005in. in depth. The machine is manufactured by the Manufacturers' Consulting Engineers of Syracuse, N. Y.

REAMER HOLDER

A very unusual reamer holder has been placed on the market. The holder is not intended to float, but operates on a different principle. In order to ream a straight true hole it is assumed necessary to hold the rear end of the reamer in line with both the centre line of the machine spindle and the hole to be reamed. To accomplish this a bushing or adapter is provided which fits in the hole in a turret. On the face of the bushing a large flange is provided and to this is fastened by three cap screws a face plate. The holes in the face plate, through which the screws extend are larger in diameter than the screws themselves, permitting a certain amount of movement. A cone-shaped centering plug extends from the face plate and is integral with it. In using this equipment on a turret lathe the work is first bored, then faced a short distance from the hole and the corner chamfered so as to provide a proper bearing for the taper plug on the front of the face plate. The three screws are loosened and the coneshaped centering plug is placed in the hole in the work. As soon as this cone plug enters the bored hole it brings the face plate concentric with the spindle of the lathe. While the plug is held tightly against the work, the cap screws are tightened so as to secure the face plate. The turret is then backed away, the cone is removed and the reamer holding sleeve is inserted in its place. This sleeve maintains the reamer securely in position and insures that its rear end will be in line with the centre line of the work and of the machine spindle. The reamer holder can be disengaged in order to fit it to other reamers. Ordinarily the entire reamer may be passed through the adapter sleeve so that only that portion of the reamer necessary to make the cut is required to overhang. The reamer shank thus projects into the turret. The face plates, the holder sleeves and the centre plugs are all interchangeable and only one plug is ordinarily required for a group of machines. The reamer holding sleeves can be supplied in sizes to suit the reamers that are used. The tool is manufactured by the Marvin & Casler Co., of Canastota, N. Y.

INTERESTING WOODWORKER

A woodworking machine which is a complete, portable little planing mill for performing 14 different operations has been placed on the market recently. This machine was brought out to meet the demand for a light tool to do the

Universal Woodworker

work of a large machine. It can be taken "to the work" and may be located on a bench in any part of the shop. Among the many operations performed are: cutting like a big swing saw, square cuts on long pieces, dadoes out for shelves and racks, grooves and plows for furniture building, screens, window frames, stairs, etc. Many other uses are found for this interesting machine. It is of a convenient size for economic service in factories, hotels, apartment stores, and places where considerable box making or crating is desired. The bench space required is one square yard, saws of 6-8-10 in. are used at a speed of 4,200 r. p. m. The weight of the machine is 245 lbs. It is manufactured by the Hutchinson Mfg. Co., Morristown, Pa.

ELECTRIC ATTACHMENT FOR HOISTS

Recently there has been placed on the market an electric device for operating hand power hoists of five ton or larger capacity. It is an electrically driven machine that may be suspended in the bight of the operating chain. It has a capacity of overhauling 138 feet of chain per minute, with a chain pull of 150 pounds, thus overhauling the chain about four times as fast as a man can do it. The machine consists of a cast iron housing in which is contained a hardened worm and worm gear running in oil and driven by a ¾h. p. motor attached to the frame. The worm wheel shaft carries a grooved sheave with a rubber tread, which is V-shaped and will fit any size and pitch of operating chain giving sufficient tractive effort to prevent slipping. The machine is counterbalanced so that it hangs with the centre of gravity in the plane of the operating chain. Current may be supplied from any convenient lamp socket by a flexible conductor. A plug socket for attaching the flexible conductor, and a reversing switch that enables the motor to be run in either direction, is mounted on the machine. The apparatus is intended for use on hand operated equipment where it is desired to obtain faster and easier operation. It is useful in many places where it would not pay to install an electrically operated crane. The apparatus is marketed under the trade name of "Handiman" and is not in itself a hoist, but simply a portable machine that may be carried from place to place and used to operate a number of hand hoists. The machine weighs 165 pounds and is manufactured by The New Jersey Foundry and Machine Co. of New York City.

BENCH WET-GRINDING MACHINE

A bench grinding machine that has recently been adapted to wet grinding has recently been placed on the market. The machine is thus suitable for use of cylinder re-grinding shops and piston distributors, where rapid production on a semi-manufacturing basis is necessary. The wheel head is equipped with a half horsepower motor and carries an 8 x ¾ in. abrasive wheed. There is a tool holder mounted on the front of the wheel slide which can be swung into, and out of, the operating position without changing the position of the set-up or dismounting the grinding wheel. It is thus possible to remove a considerable amount of metal by the turning tool and then swing the tool out of position and finish the work on the grinding wheel. The work is ordinarily held on a bull centre or an adapter, and the tail-stock centre is used as an additional support. The grinding wheel does not rotate while the lathe tool is cutting. The tool holder can be entirely removed if it is not required. An adjustable stop is provided to maintain the proper position of the table. The machine is adapted to the grinding of wrist pins, valves, reamers and such small work requiring either cylindrical or taper turning operations. It is very useful in tool rooms and experimental shops. The weight is about 600 pounds. The grinder is manufactured by the Van Norman Machine Tool Co. of Springfield, Mass. It is known as their No. 2 machine and is marketed under the trade name of "Re-li-o."

A Start In The Right Direction

IN COMMENTING upon the fact that the United States Railroad Labor Board has begun to reduce the pay of rail workers, the Toronto *Mail and Empire* says that, as usual, the common laborers are the first victims, and asks why the poorest paid workers should be the first to suffer. Our contemporary in asking this question is assuming that the least paid workers are the poorest paid.

The contrary is in all probability the case. The common laborer at the present time is, in many instances, the highest paid worker in the community. The skilled worker may be receiving more actual money (and in some cases it is very little more) but, in proportion to his skill which it has perhaps taken him years of apprenticeship and application to acquire, he is far more poorly paid than the common laborer, who from lack either of intelligence or of application has never been able to make himself a skilled man.

The conditions which the writer in the Toronto paper would apparently like to see continued are responsible in no small degree for the unrest in the labor world at the present time. Skilled workmen such as carpenters and machinists who have had to devote several years of their life to make themselves competent men in their line and who are subject at certain periods of the year to unemployment, see men with steady jobs at street-cleaning or garbage-collecting getting nearly as much money as they themselves can earn.

Small wonder that they are discontented and feel that they are suffering from an injustice when they see that their years of hard work and application have given them no advantage over the idler, the drifter and the casual laborer.

Proportionately, the latter are the highest paid workers in the community, and, as it is inevitable that before we can hope for a return of prosperity such anomalies in existing rates of wages as we have referred to will have to be removed, we welcome the news that the Railway Labor Board have had the courage to make a start in this direction, unpleasant though the duty may be.

Who is Responsible?

THOSE WHO are in the habit of girding against what they term "the capitalistic system" would do well to consider some recent remarks of Lord Leverhulme and to ask themselves whether it is not themselves rather than the "system" which is at fault and responsible for the evils they deplore.

"Shall we take the growth and development of a capitalist," he says, "and see how he begins?

"I venture to say, if you will search back during the last two thousand years, you will come to this germ growth of a capitalist. It has been so in all ages; it is so to-day. We will take six young men entering any trade, engineers, or whatever it may be, at the same time, approximately the same age. One of them takes the view of what is outside the wage envelope—he is hard-working and saves. The other five, like the man with the one talent, have no sin; they are simply pleasure-loving, easy-going, and they never think very much about to-morrow. When their money comes it is spent, but they have no sin, no vice—they are merely pleasure-loving, easy-going.

"Now, the young man who saw more outside his wage envelope, saves and prepares a home and marries the girl of his choice. In process of time he is made a foreman; a little later on he is made a manager; a little later on he is an actual employer himself, and further, later on in life, the other five—who have committed no sin, remember—seeing him go past in his motor car, with a smiling wife and bonny children beside him, wonder how it is, and they come to the conclusion that it is the capitalistic system that has placed one man in the motor car and left the other five just where they were when they began. They adjourn to the nearest public house and pass resolutions against the capitalistic system, and determine it must be overthrown immediately, if not sooner."

Behind the Scenes

THE TELEPHONE has become one of the most important assets to business generally. Without it, many transactions would be delayed, and in a thousand and one ways, the wheels of industry would become clogged. The proof is self evident when a severe storm occurs. Lines are down, communications cut off, and the usually calm and efficient business man is helpless.

Take for example the big storms of February, March and April of this year. During February approximately 1,175 poles on the long distance lines, and 350 on rural lines were destroyed. To effect repairs, some 100,000 pounds, or 665 miles of iron wire, and 1,430 miles of copper wire were required.

No sooner was this trouble cleared up than the March storm made its appearance. In this case about 4,000 poles on long distance lines and 1,550 on rural districts were broken or otherwise destroyed. This took 830 miles of iron and 2,860 miles of copper wire. Then to cap the climax, the April storm added its toll.

Summed up, the three storms involved a loss of 7,215 poles and 6,000 miles of wire, or enough to reach nearly one quarter around the world.

What of the interruption? Considering the damage, the delay was very slight, and shows the wonderful organization behind the service. Their forces remind one of an army, well generalled, for the moment undue pressure occurs at any point on the line, reinforcements are rushed to the spot, filling the breach in short order. Modern improvements have helped this reconstruction work, and the experimenters in various laboratories must not be overlooked when commenting on the good work performed. We owe a great debt to our telephones and the figures quoted may help you to sympathize with central the next time you cannot get the desired number as quickly as you think it should be secured. It may be something beyond her control.

Building Helps to Keep Steel Market Firm

Canadian Steel Prices Steady and Demand Good—Pig Iron Stationary—Non-Ferrous Metals Show Added Strength—United States Sheet and Tin Plate Mills Have Opened Books

VARIATION IN PRICE OF IRON AND STEEL BARS

WITH the exception of a slightly better tone in the non-ferrous metal field, Canadian markets remain much the same as last week. Iron and steel lines continue to move briskly, and so long as the present building activity keeps up, we can expect this market to remain firm.

Prices on bars are erratic, ranging between $2.75 to $2.90, but the capital buyer can usually secure the lower figure. In another week however, the $2.90 price may be standard as the tendency is upward. Those requiring bars would do well to place their orders at once.

Pig iron is simply holding its own. The production rate is not high, neither is the demand, so conditions are fairly well balanced. Some furnace operators are beginning to wonder how much longer the coal strike will last. Their coal is getting a little low and they are none too sure of future sources of supply.

Non-Ferrous metals are stronger in some quarters. Prices are firmer, and the demand has improved slightly in Toronto and district.

Scrap metals are not very brisk, but prices are firm. Dealers feel the market is bound to break soon, and believe the tendency will be upward. At present however, the only thing that is firm is the price.

Steel pipe is in good demand, and deliveries are getting more delayed every week. The delivery on sheets is also poor and in both cases,prices are decidedly firm.

Machine tools are holding their own but small tools and supplies have tapered off slightly in some quarters. Other localities report good business in the latter mentioned line. This market fluctuates very much at present.

Malleable fittings are now priced per piece. This became effective June 1. The demand is good, and it is expected that the new arrangement will simplify matters all round. Oils and waste are also firm.

In the United States, sheet and tin plate companies have opened up their order books for new periods at unchanged prices. Sheet bookings were opened by one firm for July only. This is a form of self protection as it leaves them free to advance quotations later.

Production of steel ingots for April and May totalled 6,000,000 gross tons. against 4,900,000 in February and March. This shows a 23 per cent. advance. Steel prices are strong, but the market is decidedly quiet, apart from the placing of orders against later requirements.

The automobile industry is not buying much steel, although their production rate has practically reached a record. The pig iron market is stagnant. Consumers are waiting for an expected readjustment in price when coke supplies become less scarce. Lake Superior iron ore prices have not yet been announced, the matter being held back by rail freights not being adjusted up to date of writing.

Toronto

June 7, 1922.

THE LOCAL market remains practically the same as last week, the only changes being a strengthening in the non-ferrous metal section, and a slight tapering off in the demand for small tools and supplies.

Iron and Steel.—These two lines continue strong. Building activity is responsible for the majority of business moving, and sheets and pipe are particularly active. Reinforcing material is also selling well, in fact all goods entering the building field.

"What price are you selling bars at?" seems to be a popular question among dealers this week. One merchant told us the price was positively $2.90, but in spite of this apparently sure tip, we know bars are still being sold at $2.75 by a few dealers.

From present outlook, it would appear that $2.90 will be the standard quotation in another week, but we can definitely state that bars were selling at $2.75 when this letter was written. Those requiring any bars had better send for them quickly if they want to get in on the low figure. The volume of orders is keeping up very good, and dealers generally are not complaining. Following are present quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—There is no change in the pig iron situation. The price remains $29.15, and the demand keeps up fairly steady. The production rate is not high, however, as producers are getting ready to face a coal shortage. If matters are settled within the next two months, it will ease the situation, but should the strike last longer than the above mentioned period, the furnaces may find it difficult to keep going.

Non-Ferrous Metals.—There is a much stronger tone on this section. Copper and red brass are particularly active, but yellow brass and white metals still remain weak.

Business is now being closed, that two months ago would have met with a chilly reception. Prices have firmed a little, but nothing to feature, the change being from half a cent, to one cent a pound. As one dealer put it, "The market is certainly stronger than it has been for some time past, and while there is no definite advancement, there is enough extra business moving to give us encouragement." Following are quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals.—A slightly stronger tone is present, but very slight. The demand while better, is erratic, so we cannot report any definite improvement in this section. Following are present dealers' buying prices.

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools.—The demand for machine tools remains unaltered. There are no large orders being closed but a certain percentage of smaller orders continues to come in. One dealer reports that covering a space of three months, his last quarter was about 33 per cent. ahead of the former quarter. Even this, however, does not say very much, because the former period was very poor. One thing sure, dealers are all out fighting for business, and keen competition is the rule.

Small Tools and Supplies.—This section has proved a disappointment during the week. Every merchant interviewed, reported a drop during the week, but one dealer showed us figures for an extended period which were comforting, for the increase over a corresponding period last year, was more than 20 per cent. One merchant commenting on the situation said: "The demand is erratic. Next week there may be an influx of orders, and it is quite probable that the total figures for June will still be ahead of May."

Transmission equipment does not seem very brisk, while drills, reamers, cutters and taps are about best of all. This may not be true in all cases, but

taking the average, this is the way it shapes up.

Pipe Fittings.—As reported last week, a new price list has made its appearance on the market. From now on the price will be set per piece, and as stated on the table below, the discount will be 70/5. The demand is good, building activity being chiefly responsible for the increased orders. Following are a few of the new prices, showing how they are arranged.

NEW MALLEABLE FITTING LIST

	Black	Galv.
1 in. elbow	0 32	0 53
2 in. elbow	1 05	1 70
1 in. tee	0 43	0 70
2 in. tee	1 45	2 40
1 in. coupling	0 33	0 53
1 in. locknut	0 15	0 23

This shows the new style of pricing. Discount to dealers is 70/5 off list.

Steel Pipe.—This market is very strong. The lucky manufacturer is the one who has pipe in his plant racks, for deliveries are slow, and getting worse every day. The added tariff on pipe will not affect the industry or demand to any appreciable extent, and dealers will likely have to sell on a closer margin of profit.

Oils and Compounds. — These lines continue at about the same rate. Dealers and garage men are the principal buyers, but a certain amount of material is being purchased by firms direct. Waste is also moving at a fairly good rate, but prices remain unchanged. Following are present quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	10 80
Pure turp., single bbls. gal.	1 40
Linseed oil, raw, single bbls.	1 15

WASTE

XXX Extra	16	Atlas	13
Peerless	21	X Empire	13
XX Grand	15	Ideal	18
Superior	20	X Press	11½
X L C R	14		

Colored

Lion	12	Fancy	13½
Standard	10½	Popular	9
No. 1	13	Keen	7½

Wool Packing

Arrow	30	Anvil	20
Axle	25		

Washed Wipers

Select White	13	Dark colored	13
Mixed colored	14		

Boiler Tubes.—The demand keeps brisk, and prices have been revised. The new list appears below. Roughly speaking the average reduction is about 1 cent to 2 cents per foot. Following are present quotations:

BOILER TUBES

Size	Seamless	Lapweld
1 in.	18 00	8
1¼ in.	20 00	
1½ in.	19 00	
1¾ in.	20 00	
2 in.	19 00	16 00
2¼ in.	34 00	19 00
2½ in.	43 00	19 00
3 in.	29.00	24.00
3½ in.	22 00	26 80
4 in.	25 00	31 25

Montreal

June 7, 1922.

THE STIFFENING in prices of many lines, reported last week is still being maintained. The amount of business passing is also about the same. Iron and steel products are moving nicely, and are quoted at the same prices as last week. Pig iron is very quiet, also the machine tool market. Supplies are still moving well. Non-ferrous metals are firm in price, and the scrap market is improving slightly.

Iron and Steel.—Business does not seem to be affected by the fact that local jobbers last week increased their prices from $2.75 to $2.90 base. Very keen competition is still present and prices are sometimes shaded. The quotations of the mills to jobber still stand at $2.50 base Montreal, and to the large consumer $2.30 base. Transactions at this latter figure are made with the provision that the steel is for consumption by the purchaser and not for resale. Thus, none of the $2.30 steel finds its way to the jobber. It is understood that there is some stock of steel held locally by jobbers, which was purchased at the time of the lowest quotations made by local mills, and others some two months ago. This can be disposed of at a lower figure than $2.90, and may be responsible for some of the price shading.

Building is very active and is keeping up the demand for sheets, both black and galvanized, and a variety of small steel products. A small tonnage of structural sections is also traceable to this source. Local supplies of galvanized sheets come largely from British mills and some jobbers claim it is difficult to keep their stocks up, as the demand is great. Merchant bars show a gradual improvement, while there is a fair tonnage of structural steel moving.

Boiler tubes are still very firm but no actual advances have been made. The railways have not yet come into the market for rails, tie plates, joints, etc., this being a great disappointment in some quarters.

The quotations named by local jobbers are as follows:

Iron bars	2 90
Steel bars	2 90
Reinforcing bars	2 90
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Last week was very quiet for pig, but matters are less active this week. Prices are unchanged, No. 1 pig being offered at $31.80. A little British iron is still coming in, but the total sales from all quarters are small.

Machine Tools and Shop Supplies. — Dealers report that machine tool sales are very disappointing. The only orders being secured are for small tools. Wood working tools are moving a little better than iron working machines. If the new budget is made effective as it now stands, it will not make much difference in the prices of machine tools. It will mean at most, a two or three per cent. advance.

Supplies are still moving nicely, some shops coming into the market in a very satisfactory way. One jobber in machine tools and supplies reports he is not selling a machine tool, but is turning over about what he considers fifty per cent. of his best pre-war days. When this figure is gained from the sales of supplies, he thinks it shows up pretty well. In this case everything is in demand from rivets, set screws, and other small articles, up to portable machines. When the demand for machine tools returns, he expects to have a record turnover.

Other firms report business very good, and say that May was a better month than April.

Non-Ferrous Metals.—The quotations on all non-ferrous metals are firm, but the business offering is not improving to any marked extent. Copper is very firm, and tin is up half a cent. Following are local quotations:

Lake Copper	17 25
Electric Copper	17 00
Castings, Copper	16 75
Tin	35.50
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metals.—The scrap metal market is firm, but with small holdings. The better demand for scrap in the States, and recent advances in nearly all metal quotations, have tended to firm up local quotations. Business is improving a little each week. The following is a list of prices asked.

Copper, light per 100 lbs.	9 50
Copper, Crucible	13 00
Copper, heavy	13 00
Copper Wire	13 00
No. 1 composition	10 00
New brass cuttings	7 50
Red brass turnings	8 00
Yellow brass turnings	5 25
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	13 50
Boiler plate, per gross ton.	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable	10 00
No. 1 machine cast iron	23 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	19 00
Mach. shop turnings	4 00
Stove plate	19 00
Cast boring	3 50

Pittsburg

ON JUNE 2 the American Sheet and Tin Plate Co., (Steel Corporation) opened its order books for new periods at unchanged prices, $4.75 for 100-pound coke tin plate, $2.40 for blue annealed sheets, 10 gauge; $3.15 for black sheets, 28 gauge; $4.15 for galvanized sheets, 28 gauge, and $4.50 for automobile sheets, 22 gauge.

In tin plate, order books were opened for the usual periods, second half of the year in the case of manufacturing consumers, and the third quarter for jobbers. In sheets there was an unprecedented action, as books were opened for July only. The old practice was commonly to name prices for six months at a time, but of late the practice has been to take the market a quarter at a time.

The book opening was unusually late this time, due no doubt to some uncertainties growing out of the coal strike. The majority of independent sheet pro-

ducers have been disposed to seek higher prices, and in the past three weeks several have "announced" advances, most of these so-called advances being $5 to $7 a ton. On account of increases in costs there was some basis for making an advance, but the Steel Corporation was reluctant to do this on account of the increases in cost being due largely to the coal strike, the essence of which is an effort on the part of coal producers to get costs down.

Then there has been plain evidence in the market that while a number of independents had announced advances in their prices, there had been much selling into the third quarter, if not through the whole quarter, at the old prices. These, presumably, are the considerations that moved the corporation to continue its old prices, but to limit sheet sales to July so that if necessary an advance could be made later.

Tin Plate.—Most of the independents were eager for an advance in price from the $4.75 figure, although in the past fortnight, when it appeared unlikely the leading interest would not make an advance, some of the independent mills have refrained from expressing an opinion that the market ought to go up. The reaffirmation of $4.75 as the regular price would mean an advance to some of the mills, if they adhere to the price, for many sales were made for the present half year at well below $4.75, perhaps down to $4.50. Mills that have made such sales can secure an advance now by simply sticking to the regular price.

It now seems to be well established that sheet bars are to be $35 for third-quarter, against $29 for the first-quarter of this year, and the current quarter. In seeking an advanced price for sheets, over the present $3.15 basis, some of the mills urged the $6 a ton advance in sheet bars, but it is to be noted that the bi-monthly wage settlements showed average invoice prices January to April inclusive, on the basis of about $2.85, although "the market" had been $3.00 for months up the beginning of April when the advance of $3.15 occurred.

Thus at $3.15, mills would be obtaining $6 a ton more for sheets than in the early months of the year, with a $6 advance in sheet bars. No doubt the sheet mills ought to get an extra margin, but the experience of the years before the war was that frequently they did not advance in the sheet market frequently passing simply to the steel mill.

Heavy Steel Production.—Production of steel ingots in April and May totaled fully 6,000,000 gross tons, against about 4,900,000 tons in February and March. That is, in the first two months of the coal strike, the mills made 23 per cent. more steel than in the two months before the coal strike, which is as strong an answer as could be made up to this time to the threat of the coal strike interfering with steel production. The rate of production in the past couple of weeks has been about 38,000,000 tons a year, against a rate of about 35,000,000 tons.

It has been no secret that a part, and probably a considerable part, of the strength of the steel market in the past few months has been due to the coal strike, making buyers of steel fearful that they might not secure all the deliveries they would need. The record of production to date, and the continuance of a high rate of output now, suggest that there is no occasion for uneasiness on this score, and perhaps that is the reason the steel market has been growing quieter and quieter in the past three or four weeks.

The steel market is now decidedly quiet, apart from the placing of orders against new wants arising, particularly in connection with freight car orders and contracts for fabricated steel. The freight car buying keeps up quite well, but fabricated steel is growing quieter. Fabricated steel contracts let, in proportion to capacity of the fabricating shops, amounted to about 77 per cent. in March, 99 per cent. in April, and 66 per cent. in May.

The automobile industry does not seem to be buying much steel at the moment, although it has been producing cars in the past few weeks at nearly, if not quite a record rate. Probably the factories are uncertain as to their operating rates after about July 15. The heavy buying of automobiles in the past few months has surprised almost everyone, perhaps even the automobile makers themselves. Production of automobiles, trucks and accessories at the rate of the past couple of months absorbs a tonnage of steel equal to about 5 per cent. of the total production of finished rolled material at the present time. Most people, without investigating, would guess a much higher percentage.

Steel prices are very strong at base rates, while there is not as much paying of premiums to secure early delivery as was expected. Even in merchant steel bars and sheets the tonnage going at extra prices is only a small percentage of the total production. Regular prices are: Bars, shapes and plates, $1.60; hoops, bands and hot rolled strips, $2.25; standard steel pipe 71 per cent. basing discount; blue annealed sheets, $2.40; black sheets, $3.15; galvanized sheets, $4.15; automobile sheets, $4.50; tin plate, $4.75; plain wire, $2.25.

The curious condition remains of there being two prices on nails, as about the middle of April all the independents advanced from $2.40 to $2.50. For a time it was expected the Steel Corporation would advance also, but in the past fortnight this prospect has become slim.

Pig iron remains quotable at $25 for Bessemer and basic, and $24 to $25 for foundry, f. o. b. valley furnaces. The market is stagnant, as consumers expect a readjustment in prices when supplies of coke become less scarce. Connellsville coke is quotable at $7.00 for furnace and $7.50 for foundry, with a light turnover.

Lake Superior iron ore prices for the 1922 season have not yet been developed, the matter being held back by the rail freights from mine to lake not having been adjusted. The ore interests have been seeking a 25-cent reduction.

Canadian Vickers To Build Mining And Milling Equipment

CANADIAN Vickers, Ltd., have recently undertaken the manufacture of mining, power and general industrial machinery at their Longue Point works in Montreal. The plant is well equipped with heavy tools and handling facilities suited for the economical manufacturing of this class of machinery. Agreements have been made with several American firms to manufacture a wide range of equipment, including many items which heretofore were not built in Canada. In selecting a line to manufacture the most modern designs have been chosen, and all of these designs call for a high standard of workmanship.

The firm fully expects that the demand for equipment to develop Canadian natural resources will increase rapidly, and with manufacturing facilities, skilled labor and technical direction available in the country, the necessity for importing the major part of the mining industries' requirements can be avoided, and a material saving made to the purchasers on duty and freight.

A special technical organization has been built up to work in co-operation with the engineering staffs of the firms whose lines are being manufactured at the Canadian Vickers' works. The marine department has commenced the manufacture, under the Hickman Patents, of sea sleds, a new type of high-speed, shallow-draft motor-boat with surface propellers. These craft have a remarkably high deadweight carrying capacity for given speeds and powers, as compared with the usual type of hull construction and propeller arrangement. The ability of these craft to navigate at high speeds, in rough water that would swamp a standard type of boat, may solve the problem of transporting men and supplies to isolated prospects or construction jobs on inland waterways and lakes in all weather. The shallow draft and surface propellers will permit the navigation of streams and rapids prohibitive to an ordinary motor boat.

As the operating conditions of cranes necessitate frequent and rapid starting, stopping, and reversing, an economical and efficient method of controlling the speed of crane motors is a great desideratum. A crane controller of modern design is of the drum type, consisting of a combined starting, reversing, and speed-regulating switch, and may be safely operated by unskilled labor without sustaining or causing damage to the electrical equipment.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

How U. S. Views St. Lawrence Canal Project

Governor Miller, of New York, Demands Thorough Examination of Scheme—Would Be Willing to Spend a Million Dollars for This Purpose and Promote Carrying it Through if Report Favorable

THE ADVISABILITY of raising and spending several hundred million dollars in making the St. Lawrence River navigable for ocean-going craft and thereby making virtual seaports of the cities on the Great Lakes has lately been widely discussed in the United States. The project appears to be regarded by New York as one actuated by hostility to its interests. Darwin P. Kingsley, president of the New York Chamber of Commerce, addressing that body recently defined it as honest hostility based on imperfect information and local ambitions and not as dishonest hostility actuated by political motives. The plan is nominally approved by eighteen states which include roughly all those having no seaboard outlet. Its appeal, however, in Mr. Darwin's opinion rests largely on an alluring suggestion. To tell Chicago, Duluth, Cleveland and Milwaukee that they ought to be and can be great seaports is to fire the imagination of their people, he considers.

In a debate before the National Rivers and Harbors Congress in Washington, Governor Nathan L. Miller, of New York, expressed his willingness for Congress to appropriate a million or more to have a thorough investigation made by impartial experts and, he declared, if they pronounced it feasible he would support it no matter what it might cost. At the same time Governor Miller offered an alternative plan in suggesting that the Mississippi River and its branches be improved so that the Middle West might ship its products by barge to New Orleans and thence to foreign ports, thus saving the heavy railroad charge of assembling such freight at the Lake ports for export via the St. Lawrence River.

Governor Allen, of Kansas, dwelling upon the "tragedy of transportation" under which he said the Middle West was suffering, declared that the eighteen states in favor of a St. Lawrence Ship Canal produced 70 per cent. of all the wheat grown in the United States, 66 per cent. of the corn, 80 per cent. of the oats and 70 per cent. of the barley. He argued, relative to bringing the sea coast, 1,200 miles nearer to the Middle West, that, "without any intention whatsoever to injure New York, we do say that if that sea coast is a good thing for New York, we would like to have it also." He referred to the statement that New York would be called upon to pay 30 per cent. of the cost of the canal as merely New York's "quaint way of explaining that she gets more than anybody else." As to the New York State Barge Canal, which is placed in some jeopardy by the St. Lawrence project and which is capable of transporting 10,000,000 tons each way annually, he asserted that the transportation demand of the eighteen states involved is 200,000,000 tons. Consequently "there is nothing in the Barge Canal that competes with our project. The Buffalo papers have been screaming at us in the Middle West, 'Come on here! Here you have it now!' Well, we are not bound for Buffalo. We are bound for Liverpool."

Advocates of the canal maintain that it will save the Middle West $350,000,000 a year and that to offset the cost of the canal will be the development of 1,400,000 hydraulic horsepower to be marketed under the jurisdiction of the United Commissions of the states in which it is distributed.

Governor Miller questioned these and other figures, declaring: "There is no market or practically no market whatever at the place where this power will be developed; and there are many engineering features yet to be studied before it is determined where that market is going to be and how much it is going to cost to get the electricity to that market. At any rate, it is going to take years—how many I do not know—during which fresh charges are going to pile up.

"But they give it out over the country that this thing can be done for $250,000,000 a mere bagatelle, less than they will save in one year on wheat. And then they want to commit the government and the Federal treasury to the assumption that in some way not designated, not even studied, water power is going to pay for it."

With regard to the statement which had been made that the Middle West was seeking an outlet for 200 million tons of products, Governor Miller stated that in the banner year of 1920 the total export and import tonnage of the United States was only 54 million tons.

It was also his contention that a 30-foot instead of a 20-ft channel would be required for the canal and that this would cost at least $500,000,000. The fact also that the advocates of the plan were trying to rush the proposition through upon the assertion that it would cost only $250,000,000, upon a superficial examination only, and upon the assertion that it was not necessary to consider the deepening of the channels of the Great Lakes, was an indication to him of a lack of good faith. It showed, in his opinion, that they were not willing to have the facts examined, and that they were trying to commit the government to something that neither they nor anyone else had computed.

FEEL THAT CONDITIONS ARE MUCH IMPROVED

The industrial centres of Eastern Canada display a more hopeful spirit, according to a monthly commercial letter of the Canadian Board of Commerce.

A number of manufacturers in Western Ontario find that the amount of goods produced during the winter is insufficient to meet the present demand, and in consequence are extending their operations. Knitting and woollen mills, and brass and stove foundries, located at a number of points, report activity, and in some cases difficulty is being found in keeping pace with orders received.

In important centres, such as Hamilton, it is stated by manufacturers that business is improving, and that prospects are better now than at any time during the past year. The majority of factories in Hamilton are taking on additional hands, and the unemployment situation is consequently considerably easier. At Shawinigan Falls, one of the important industrial centres in the Province of Quebec, business is active, and there are no complaints of unemployment.

There is noticeable improvement in the iron and steel industry. Official returns indicate an increase in the output of domestic pig iron during March to a total of 41,733 tons, composed of 25,974 tons of basic pig iron, 10,123 tons of foundry iron, and 5,636 tons of malleable iron. With the exception of 71 tons, the output of basic iron was all used by the producing firms. Foundry iron, on the other hand, was produced largely for sale, the total under this heading being 10,080 tons, with only 43 tons made for the use of the firms reporting. Compared with the preceding month the production of basic iron was only slightly higher, but the output of foundry iron was almost 2,000 tons greater than in February. The malleable iron made during March was the first produced this year.

BOOKLETS

A booklet, known as circular 1579-B, containing general information and technical data for cutting micarta gears and pinions, has recently been issued by the Westinghouse Co. for distribution among gear cutters. The book contains a great amount of useful information for gear manufacturers.

News From the Industrial Field

Sault Ste. Marie, Ont.—A dock to cost $60,000 is being constructed by A. B. McLean & Sons.

La. Cie. Electrique of Papineauville, Que., will construct a power house and dam costing $30,000.

The C. P. Railway is contemplating the erection of freight sheds at Yorktown, Sask., at a cost of approximately $70,000.

R. A. Thompson is going to erect an addition to his flour mill at a cost of about $10,000.

Allison Peck Hillsboro N. B. is contemplating the erection of a woodworking factory to cost about $10,000. Moncton N. B. is spoken of as the site.

Welland, Ont.—A cold storage plant may soon be erected by the St. Thomas Packing Co., St. Thomas, at a cost of $50,000.

A bridge may soon be erected over the Pembina River, north of Cherhill, Alta., if present plans go through. The dept. of public works, Edmonton, is interested.

Tenders will be called shortly for repairs to dry dock retaining wall to cost $25,000 for Halifax Shipyard, Ltd., Halifax, N. S. C. A. Fowler & Co., are acting engineers.

The Canada Machinery Corporation, Galt, through Chas. A. Strelinger Co., Windsor, have secured the contract to install three lathes, a bandsaw, and grinder, in the technical department of Walkerville Collegiate.

The machinery and equipment of the Union Iron & Metal Co., Toronto, is being sold by tender. Bids will be received up to June 14. Further information can be secured from F. C. Clarkson, trustee, Toronto.

A writ has been issued by the Trust & Guarantee Co., Toronto, asking for an order for its appointment as receiver and manager of the Ontario Smelters and Refiners, Welland, Ont. Default of interest on outstanding bonds is the reason given.

Niagara Falls, Ont.—Tenders will be called for construction of asphalt plant for this city. J. C. Gardner is the man to write to. Falls Machinery & Supplies of the same city is contemplating the erection of a warehouse and office.

A Hydro-Electric power plant will be constructed at Thessalon, Ont. This will consist of dam and power house, 200 h. p. turbine and generator, and three miles of transmission line. It is also proposed to electrify the pumping station by installing motor-driven pump and gasoline-driven fire pump. Tenders will be called by James Proctor and Redfern, Engineers, 36 Toronto St., Toronto.

H. C. Crow, for several years sales manager of the Canada Metal Co., Toronto, has resigned to devote his entire time to his mining interests.

A fire at the Don Valley Paper Mills, Toronto, destroyed approximately $100,000 worth of property a few days ago. Over $250,000 worth of machinery and stocks was saved.

Halifax, N. S.—Exports from this port for January, February and March of the present year totalled $14,235,027. The 1921 total for corresponding period was $11,063,553, or $3,171,474 lower.

W. Bruce, manager of the Empire Brass Foundry, 128 Wellington St., Montreal has plans made and will receive tenders on additional work and alterations to present buildings. No closing date has been set.

The penalty clause of the recently proposed engines bill has been removed, and in the modified form the bill to incorporate an association of engineers in Ontario has finally passed through the committee of the House.

Harold F. McCormick, has resigned as head of the International Harvester Co. Alexander Legge, vice-president and general manager was unanimously elected to Mr. McCormick's former position.

The Canadian Steel Corporation will construct three thousand houses at Ojibway, Ont., according to J. H. Jewell, a contractor at Windsor, Ont., who claims his construction offer has been accepted. So far no definite date has been set when erection will commence.

J. H. Bertram, collector of customs at the port of Toronto, states that the customs-excise revenue for Toronto, May 1922, was $4,156,067. This is a gain of $766,067 and is distributed as follows: Customs duty and sales tax, $460,788; excise sales tax on domestic goods, $280,692, and excise duty and other collections $24,587.

The Grand Trunk Shops at Point St. Charles, are building fifteen switching locomotives of the 0-6-0 and the 0-8-0 types. The first of the fifteen is about completed. These locomotives will be used for switching, and in addition will be adopted for longer hauls across the larger cities, such as Montreal and Toronto.

Following are recent incorporations under the Companies Act: Wilson Lumber Co., Hull, Que., $300,000; Canadian Polishes, Hamilton, $750,000; Peerless Box Co., Ottawa, $250,000; Gill & Fortune Lumber Co., Trenton, $3.000,000; Carswell Construction Co., Toronto, $100.000; Nelson-Blood Trap Co. of Canada, Windsor, $50,000, and Lockhart-Westcott Lumber Co., Winnipeg, $50,000.

Messrs. Darling Bros, Montreal, who for a number of years have operated their own grey iron foundry have just started a brass foundry. The first heat was taken off the last of May.

Montreal, P. Q.—The Parker Motor Car Co, have about completed extensive tests on a small four cylinder air cooled motor car, which they expect to manufacture in the near future and place on the market at a price below $1,000.

The Three Rivers Pulp & Paper Co., is being reorganized and will be hereafter known as the St. Lawrence Pulp & Paper Co. The capitalization of the new company will be $1,000,000 8 per cent. cumulative participating, preferred shares and 40,000 common shares of no nominal or par value.

Messrs. Darling Bros., Montreal, are building three Drysdale engines direct connected to pumps for use in the ships of the Canadian Government Merchant Marine. These will be used to pump the salt water through the surface condensers. The above factory have the manufacturing rights for this equipment in Canada, and it is considered standard equipment for the previous mentioned use.

Tenders will be received up to June 30 for the supply of 42,000 pairs of motor vehicle license number plates for the province of Alberta for the year 1923. Plate to be 24-gauge metal, 4½ in x 12 in., with embossed figures and the words "Alta" and "1923" on the righthand side of the plate. Colors: White lettering on a royal blue background. Sample of plate bid on must be furnished. Submit prices to Deputy Provicial Secretary at Edmonton.

M. C. Ritchot, assistant claims agent for the Grand Trunk Railway System, retired yesterday under the pension plan of the company. Mr. Ritchot was with the railway continuously for fifty-one years. He entered their employ Jan. 3 1870, starting in the audit office. For over twenty years he was private secretary to the late Mr. Wainwright, and in that capacity met many men throughout the Dominion. Since 1907 he was assistant claims agent.

J. E. Dalrymple, vice-president of the Grand Trunk Railway, speaking on the U. S. drop in freight rates, effective July 1, says that in his opinion it will clear the atmosphere and tend to stimulate production and business. "Uncertainty in respect to freight charges always has an influence in the movement of traffic," continued Mr. Dalrymple, "particularly when the public anticipate a reduction. I look for an increase in business this coming fall, and all signs point to a revival," he concluded.

The Canadian Manufacturers Association will hold their annual convention this year at St. Andrews-by-the-Sea, B., on June 20, 21, 22 and 23. The mornings will be devoted to business sessions, while the afternoons and evenings will be given over to recreation. A large delegation from Toronto, Montreal and Quebec division is expected.

Montreal, P.Q.—Progress on the new Mount Royal Hotel is very satisfactory, and the date of completion, which was originally set at December 1, has been changed to November 1. The boilers, and a considerable portion of the heavy machinery are already on the site, and installation will be made shortly. The motors for running the elevators, etc., are being placed and connected, and it is expected within a week or ten days that all elevators will be running. This will assist materially in the completion of the structure.

The Franklin Institute of the State of Pennsylvania recently presented to Samuel T. Freas, of Henry Disston & Sons, saw, tool, steel and file makers, Philadelphia, the Edward Longstreth Medal in recognition of his invention of the "Interlocking Tooth Metal Cutting Saw." The presentation was made upon the recommendation of the Institute's Committee on Science and the Arts after a very complete investigation of the development of the inserted tooth circular metal cutting saw.

Mr. Freas, the inventor, has been associated with the Disston Co. for the past 21 years.

Montrea', P. Q.—P. Lyall & Co., construction engineers, have secured a contract for extensive alterations to the Windsor Hotel. The changes include the remodelling of the entire rotunda, all woodwork is to be replaced with marble; the Windsor Hall is to be removed to a new location which will be on the ground floor near the Old Rose Room, and five additional stories are to be added to this part of the structure. The work is to be started at once and will be accomplished without interference with the running of the hotel. The contract amounts to about $500,000 and is to be completed by the end of August.

Timmins, Ont.—According to preliminary estimates, the gold mines of Porcupine and Kirkland Lake produced upward of $1,735,000 during the month of May. A total of approximately 3,480 men were employed at the producing mines, while, approximately, 172,000 tons of ore were mined and milled. This shows that, approximately, 49 tons were handled by each man during the month, and that the average grade of ore at mines was maintained at a little over $10 per ton. The non-producers, as well as numerous others under exploration and development, are employing a substantial aggregate of men, and it would appear to be reasonable to estimate that at least 5,000 men are now employed directly at the gold mines of Porcupine and Kirkland Lake.

P. Purpur, Leader, Sask., is going to erect an elevator at a cost of $10,000.

Construction contracts awarded in Canada during May totalled $34,827,300. This is the second largest monthly figure since 1914. Residential building accounted for 45 per cent. of the May total, business building 33.1 per cent., and industrial buildings 2.4 per cent. Public works and utilities accounted for another 19.5 per cent. The trend of building costs is still downward.

Here is a good idea. Every salesman of the Canada Cement Co. is provided with a camera, and is given a dollar for every picture used. In addition special prizes of $25 and $10 are given for pictures showing most novel use and best picture respectively. A prize of $10 is also awarded for the best description of a picture showing the use of concrete.

How about this idea in your business? Can your salesmen take a picture of your product in actual use? If so, it may form the basis of the best advertising you ever started.

There was a general increase in shipments of grain down the Lachine Canal during the month of May as compared with shipments in the same month last year. There is a total increase of 2,746,133 bu. of grain. All grains show an appreciable increase except oats, which register a slight decrease. The heaviest increase is in wheat. Corn increased, also barley, rye, and flax. On the other hand farm products such as eggs, butter, and cheese show a decrease. There was also a falling off in the shipments of coal, this decrease being a very heavy one. The total for May this year was 21,725 tons, and for May last year 116,725 tons. There were no shipments of hard coal through the canal last month, while in May 1921, some 8,000 tons passed through. The number of trips during last month was 822, while in May 1921, the number was 903, which shows a decrease of 81. The total tonnage operated was 583,161, an increase of 21,945 tons. The total passengers carried were 1,649 an increase of 868 or more than 50 per cent. There was also an increase in cargo tonnage.

A report from Washington, D. C., states that there was a big decrease in the trade of the United States with Canada during the month of April as compared with the same month last year. United States exports to Canada amounted to $43,000,000 against $49,000,000 for last year, while imports were $21,000,000 against $31,000,000.

According to a statement by Thomas L. Chadbourne, attorney, at New York, a plan has been adopted whereby the properties of the Midvale Steel and Ordnance Co., Republic Iron and Steel Co. and Inland Steel Co., will be unified under the ownership of Midvale. The name of the new corporation will probably be the North American Steel Corporation. It is intended to provide $20,000,000 additional cash working capital from the sale of common stock. Negotiations are pending, Mr. Chadbourne says, for the acquisition of other properties, but, irrespective of the outcome of these negotiations, Midvale, Republic and Inland Companies propose to proceed with these merger plans.

Chambers - McCaffrey Construction Co., with head offices at Toronto, have incorporated with a capital of $50,000, to carry on a general contracting and supply business. Other incorporations are: Caledonian Construction Co., Ltd., head office at Three Rivers, P. Q., capital $20,000 to carry on the business of general contractors.

Hanover Cement & Stone, Limited, with head office at Hanover, Ont., capital $1,500,000, to manufacture and deal in cement, lime, brick, etc.

Agnew Bros. Limited, with head office at Toronto, capital $40,000, to carry on the business of contractors and builders.

McQuigge-Morse, Limited, with office at Toronto, capital $100,000, to carry on the business of a general engineering and construction company.

The Hon. J. A. Robb, Minister of Trade and Commerce states that the reason the Canadian Government Merchant Marine was not given the contract for a steamship service between Canada, West Indies, and British Guiana, was that the merchant marine officials said they could not tender for the service, having no steamers which would comply with the requirements as to passenger accommodations and cold storage, if the latter were necessary. The only tender received for the service was from the Royal Mail Steam Packet Co., London, England. The contract previously existing, was renewed for two years from April 1, 1922. It provides for a fortnightly mail, freight, and passenger, service from Halifax t Bermuda, the British West Indies and Demerara returning via the same ports to St. John, N. B. The annual subsidy is to remain at the same figure, namely $340,666.66. The contract provides that the minister may cancel it on 30 days notice, if there has been any breach in part of the contracts of any of the requirements of the agreement.

OBITUARY

William Nicholson, well-known railroad man, died at his home in Montreal a few days ago. At the time of his death he was general foreman of the C.P.R. blacksmith shop. Mr. Nicholson was born in Kingston 66 years ago, and was for several years connected with the Canadian Locomotive Works. He joined the C.P.R. in Montreal sixteen years ago.

BELIEVES CHEQUE TAX WILL HINDER BUSINESS

At a general meeting of the executive of the Montreal Branch of the Canadian Manufacturers' Association held to discuss the provisions of the Budget, there was a general objection taken to the stamp tax as a needless hindrance on business, and it was decided that as soon as possible a general meeting of the various associations throughout the country should be held to take action in this regard, and if advisable to send a delegation to interview the Minister of Finance with a protest against the proposed tax. The meeting was the first of the new executive and welcome was given the new chairman, Mr. Julian C. Smith when he assumed the chair. A long discussion took place on the proposals to demand a graduated scale of stamp taxes on cheques. The criticisms of the Budget proposals finally crystallized into the following resolution which was unanimously adopted:

"That whereas in the opinion of this meeting the provision introduced by Hon. W. S. Fielding, Minister of Finance, in his Budget address on Tuesday, May 23, 1922;

"That no person shall issue a cheque payable at or by any bank unless there is affixed thereto adhesive stamp or unless there is impressed thereon by means of a die a stamp of the value of, if the amount of money for which the cheque is issued (1) does not exceed $50, two cents; (2) exceeds $50 for every $50, or fraction thereof, two cents, and every adhesive stamp affixed to a cheque shall be cancelled by the bank at which the cheque is payable at or before the time of payment, will bear heavily upon business;

"That whereas it is believed that some more simplified method can be evolved as tax on cheques, eliminating for the business houses of this country additional clerical work and inconvenience which will be brought about by the enactment of the provision;

"Be it therefore resolved that the Montreal Branch of the Canadian Manufacturers' Association petition the executive council to make representations to the government, urging the amendment of this particular section, by some provision for the taxation of cheques which would achieve the end of the Finance Minister in raising additional monies, and at the same time could be applied to business generally with the least possible degree of inconvenience."

An addition was made to this resolution to the effect that, in the absence of more definite information, the committee would recommend that the stamp tax be imposed on units of $100, which was agreed to.

The resolution was forwarded to the Dominion executive council of the Canadian Manufacturers' Association at Toronto and a request made that it be sent to the government.

The item appearing in the daily press to the effect that the Massey-Harris Co. would shortly reopen their Brantford plant and start with 700 men is only true in part. Canadian Machinery is advised on good authority that within a week or so the plant will commence operations but the number of additional men will not exceed 400. It was also stated that the orders to be filled will be largely for stock in anticipation of late summer demand to take care of a good harvest season in the West.

J. G. Stirk, of the Stirk Planer Co., Halifax, England, will soon be in Toronto. He will arrive this week and will spend a few days with his Canadian agents, Messrs. Alfred Herbert, Ltd., 1 to 3 Jarvis Street, Toronto.

Mr. Stirk is recognized as one of the foremost planer designers of the world, and readers will no doubt recollect the description of his electrically-controlled "Hilo-Plane" which appeared July 1, 1920, in Canadian Machinery columns. In this machine Mr. Stirk made many radical changes and improvements, including a reversing motor drive, magnetic feeds, simple stroke setting device, etc.

Through the Mexican Government, the Massey-Harris Company of Toronto, has just shipped, via the Gulf of California, 20 or more "binder reapers"—huge machines, which will cut, thresh and bag the grain at one operation. James Douglass, one of the company's chief officials, has gone with the shipment to see the machines in operation and to act in an advisory capacity in connection with the order. Instruction will be given by him in the efficient operation of the binders on Mexican farms. It is stated that these machines have been shipped with a view of testing their ability on the Mexican soil, and if satisfactory results are shown steps will be taken to enlarge the trade in this direction.

Quebec, Que.—Rapid progress is being made on the construction of additional accommodation facilities at the Chateau Frontenac. The popularity of the Chateau, both as a summer and winter resort, has resulted in its capacity being taxed to the limit and the new addition, which will have a tower twenty stories high, will greatly relieve the congestion. It is exected that the new wing will be in readiness to cope with next year's tourist traffic.

St. John, New Brunswick.—Efforts are being made to secure the use of the powerful wireless plant at Newcastle, which never has been used since it was erected 10 years ago, for the purpose of establishing a broadcasting station for wireless telephony. Only the most powerful receiving sets can be depended upon to secure satisfactory results from the stations in the United States and the St. John Commercial Club is undertaking to promote the establishment of the station in this province.

SEVERAL IMPROVEMENTS TO BE MADE TO HARBOR

Mr. M. P. Fennell, general manager of the Port of Montreal, has announced a programme of extension in improvements which will be taken up at once by the Montreal Harbour Commissioners. This calls for the developing of the Jacques Cartier Pier, the high level shore wharves for sections 27 to 30 inclusive, and on the wharf at section 101 leased by the Imperial Oil Co. The first work to be undertaken will be the Jacques Cartier Pier. Improvements were commenced by the commissioners in 1919 owing to the inadequacy of the existing pier to accommodate the larger type of vessels visiting the port, and by the end of last year the addition had been brought up to the low level elevation.

Specifications for the work now to be undertaken call for the raising of the addition to high level, in order that the sheds on the old portion of pier may be extended to cover the new addition. It is expected that the work will take two or three months to complete. During the season 1921, over 637 feet of low level wharfage was completed, extending from that section known as 27, to section 30, below the old Montreal jail. The proposals for 1922 are to raise these low level wharves to the high level, incorporating such work as foundation for sheds which will ultimately be erected thereon.

The work which is to be undertaken for the extension of the Imperial Oil Company's wharf will provide additional berthage of 500 feet in length, and 30 feet in depth at extreme low water. The lower portion will be in the form of a pier 50 feet wide, to provide 300 feet of berthage with a depth of 20 feet at low water on the inside face, for the accommodation of lake craft.

COPPER OUTPUT IN 1921

The world's output of copper for 1921, according to the American Bureau of Metal Statistics, was 583,832 short tons, or 1,167,000,000 pounds compared with 1,072,674 tons, or 2,145,000,000 pounds in 1913, and a record of 1,579,545 tons, or 3,159,000,000 pounds in 1917. Stocks of refined copper in hands of American producers at the end of 1921 were 482,000,000 pounds compared with 90,000,000 in 1913 and 105,000,000 in 1912. United States consumption was 633,000,000 pounds, compared with 668,000,000 in 1913 and 705,000,000 in 1921. British consumption is estimated at 157,000,000 in 1921 against 272,000,000 in 1913 and 286,000,000 in 1912. French consumption is placed at 101,000,000 pounds in 1913, and 215,000,000 in 1912, and Japanese consumption at 126,000,000 in 1921 against 54,000,000 in 1913 and 52,000,000 in 1912.

The Prentiss Vise Co., of New York, has just issued a new illustrated catalogue and price list on their complete line of bench vises and attachments.

BOOK REVIEWS

The D. Van Nostrand Co., 8 Warren St., New York, have published several interesting and instructive technical books recently, and following are reviews on subjects which will interest our readers.

"Modern Methods of Welding," by J. H Davies, Leeds Technical School and consulting engineer. This book describes the various methods of welding, including oxy-acetylene, oxy-hydrogen, hermit electric arc, electric butt, electric seam, electric spot, and mirror welding. It also touches upon lead burning, cutting of iron and steel, also the question of eye protection when welding.

There are 39 chapters, 263 pages, and 132 illustrations, also several welding tables. The author has had 18 years experience in the welding industry and has published this work in the hopes of helping both students and present welders to more thoroughly understand their business. The price is $6.00.

"The Electro-Metallurgy of Steel," by C. C. Gow, assoc. R.S.M., M.I.M.M., B. Sc. (England), deals with the historical development of electric steel furnaces, and other phases of electro-metallurgy, including power consumption, generation and control, automatic regulators, electro-metallurgical methods of melting and refining cold charges, liquid steel refining, ingot casting, application of electric furnace to foundry practice, general principles of electric furnace design, modern types of electric furnaces, lining and repairs, and other important subjects regarding the electro-metallurgical method of melting steel.

The book has a splendid introduction, and the 15 chapters cover the ground very well. There is also an appendix describing the rapid method of analysis for bath samples. There are 132 illustrations, and 351 pages, the price being $7.50.

Everyone is talking radio these days, so the Van Nostrand Company have published a book called "Radio Phone Receiving," which is termed a practical book for everybody. Several well-known writers have contributed, and following are the subjects covered.

How radio telephoning is accomplished, tuning the simple receiving circuit, receiving the waves by crystal detectors, the vacuum tube, amplifying the music or speech, regenerative and heterodyne reception, and radio telephone broadcasting.

This book is frankly addressed to the people who are not experts, but who are anxious to learn about this new art. It is well illustrated throughout and sells for $2.50.

A series motor is well adapted for variable loads, and is capable of exerting a large starting torque, with quick acceleration, the torque rapidly increasing with the load.

Introducing

J. M. BROWN

How is this for a "take me natural" photograph? Mr. Brown, who is one of the founders of the Brown-Boggs Co., Hamilton, Ont., is no admirer of photographic studios or high-backed chairs. Upon being told we were going to take his picture he simply rose from his desk, placed his hat on his head, and stood at ease when we requested him to look for the pretty birdie.

Born in Hamilton, Mr. Brown has always resided in the same place. He can tell of some wonderful changes which have taken place since 1856, the year of his birth, and shows by the detail attending such stories that he retains a splendid memory. His education consisted of public school training until thirteen, after which he started to serve his time in a small machine shop run by S. J. Moore.

By the time he was eighteen, he became a full fledged tradesman, but before finishing his apprenticeship, advanced so rapidly that they made him foreman of the shop. He remained in this position until 35 years of age, at which time Mr. Boggs and himself decided they had worked for somebody else long enough.

They started a company making sheet metal working tools, and although they opened up in a very small way, soon branched out and added to their staff. About a year after they started 7 men were employed while during the peak days 260 men were engaged at the present plant. Some idea of the development can be gleaned from this comparison.

Mr. Brown believes a great deal can be accomplished by using ordinary common sense. "A man who is honorable and meets his obligations is always bound to succeed" he remarked, and the truth of this statement is borne out by his own experience. He always treats everybody as he would like to be handled himself, and having a strong liking for boys, he helps them in every way possible. In fact he is still much of a boy himself, and when the shop men start a ball game you can invariably find J. M. Brown either at the bat, or chasing a fly ball. Sport is not his only hobby, for he has held several important public offices, including positions on the library board, and sanitorium board.

"The Engineering Enquiry," is the title of a book published by J. W. Arrowsmith Ltd., 11 Quay St., and 12 Small St., Bristol, England. This is pocket size and is prepared for the assistance of agents, contractors, engineers, extending, commercial and technical correspondents, merchants, representatives and salesmen. The author is Tomey Thompson, who is a member of the Society of Authors, assoc. mem. of I.E.E., and member of society of technical engineers, and other societies.

The object of the book is to help men in the above mentioned positions to send complete inquiries, thus avoiding delay, and several manufacturers have already said they find it useful. Under the various headings is given what you should specify in inquiry, and where additions are sometimes necessary these are also given. This is a rather unique book and should prove very useful to men who are not technical experts, and also to students who are learning their profession. The price is 7/6d.

VERTICAL TURRET LATHE

(Continued from page 24)

time in one hour. In the above instance it gave 116 productive tool minutes in 48 minutes of operation. This is at the rate of 145 minutes per hour. Concentration of productive time is the essence of economy in production. The machining of an elevator drive thread pointedly demonstrates the advantages of turret tooling in both the main head and side head. It provides an excellent example of time economy and machining efficiency in the use of the side head. The tooling and operations are shown in Fig. 5. The actual time for machining complete floor to floor is slightly over four hours. The economy is evident from the fact that this piece was previously done on an engine lathe in 36 hours.

Try Us With a Rush Order

NEXT time you need Machinery or supplies in a hurry, phone or wire us. From the immense stocks we carry we can supply practically anything you may need at a moment's notice, and remember, your order will be carried out intelligently as well as promptly.

The Williams Guarantee backs every sale we make, whether it be new or slightly-used machinery; and this guarantee entitles you to the Williams Service—a combination that has no equal—anywhere.

Let us put your name on our mailing list for our Monthly Machinery List. Bargains every month.

SAFETY CAMPAIGN FOR EYE PROTECTION

THE GOOD effect of the educational campaign for the reduction of eye accidents in industry is reflected in the seventh annual report of the National Committee for the Prevention of Blindness which has just been issued from the headquarters of the committee in the Russell Sage Foundation Building, New York City. "Even the most ignorant workman is learning that in refusing to wear goggles he assumes a very great responsibility, not only to himself and his family, but to the neighbor who may be injured through his carelessness," says this report.

The growing interest among industrial executives in literature concerning the conservation of vision is shown in the National Committee's report by the statement that more than 3,400 sets of industrial eye accident posters were distributed during the last year and by the fact that the second edition of the committee's bulletin No. 12, a volume of 145 pages devoted entirely to eye hazards in industrial occupations was exhausted before the close of the year. This bulletin containing reports of typical cases and recommendations for safe practice, is now being revised for publication in the Fall.

The entire subject of eye hazards in industrial occupations and means of reducing or eliminating those hazards will be thoroughly discussed and brought up to date in a revised edition of bulletin No. 12 of the National Committee for the Prevention of Blindness, it is announced at the headquarters of the committee in the Russell Sage Foundation Building, New York City. The revised edition of this bulletin, which was originally issued in 1917, and which has been out of print since the latter part of 1921 will combine in one volume practically all of the available information on the subject.

FORT WILLIAM NEWS

Fort William, Ont.—Erection of a temporary aerial power cable was completed yesterday afternoon, crossing the Kaministiquia River, Fort William, from Canadian Pacific Railway elevator D to a tower erected upon the south bank, and power from the Kaministiquia power station was again supplied to industries situated in the Mission industrial area. The cable is strung high enough to clear the tops of the masts of steamers navigating the river.

Adaline V., a steam tug, sixty by eighteen feet, composite wood and steel construction, built eight years ago at Spanish River, has been acquired by Fader interests here and has arrived at the head of the lakes. Her port of registry will be changed from Sault Ste. Marie to Fort William, and she will be used in connection with local harbor work and probably in the government light-house service.

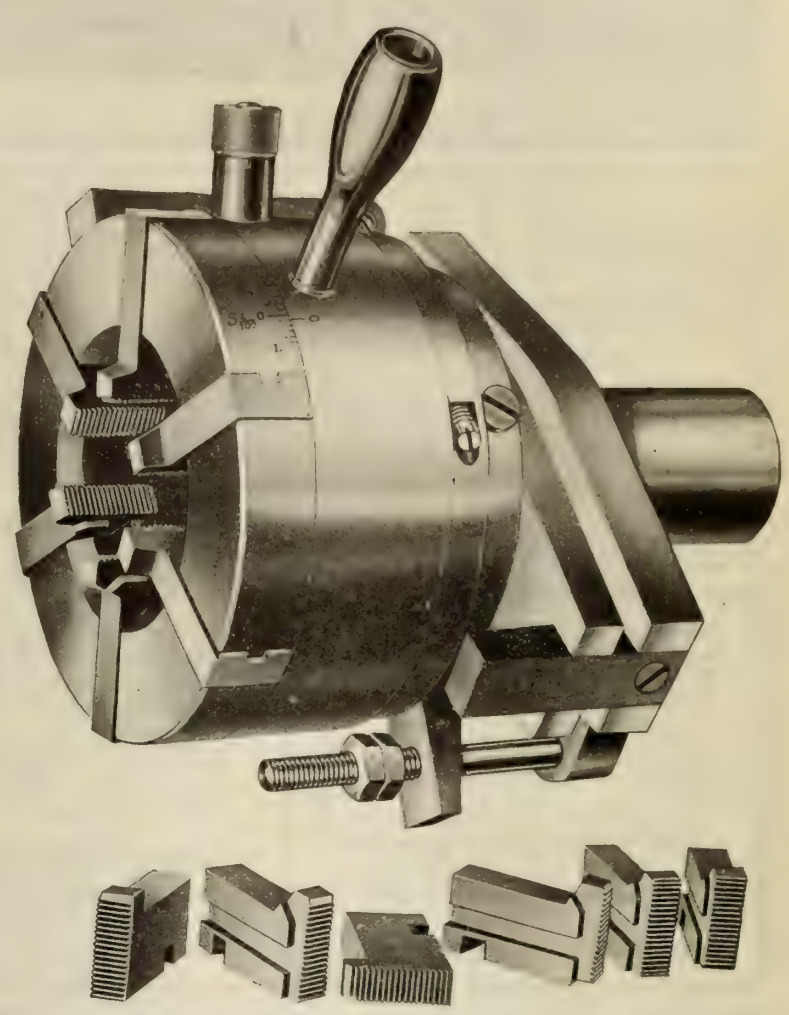
Speaking of the districts in northwestern Ontario and their mineral possibilities, Professor W. L. Goodwin, of Toronto, who has been delivering a number of lectures in Fort William and Port Arthur to special classes of prospectors and miners, stated that the Province of Ontario possessed the world's future supply of iron ore. He predicted that the huge deposits of low-grade iron ore in Ontario would be drawn upon as the high-grade deposits of the United States became exhausted. All that was needed, he claimed, was the establishment of a plant to raise the iron content of the Ontario ores, as was now being done with inferior ores to our own in the United States.

The building of small dwellings and the renovation and repair of older houses, have resulted so far during the month of May in the issuing of fifty building permits in the City of Fort William. Substantial reductions in the cost of building material and cheaper labor are proving big incentives to home-builders who having been waiting for several years to invest their money in homes.

"There is absolutely no cause to worry regarding the industrial outlook in Canada," according to N. M. Paterson, of the Paterson Grain Co., who recently returned from the Pacific Coast where he has been spending several months. He predicted that as soon as the new crop commenced to show itself in the west, business and industrial conditions would improve all over the Dominion. "The industrial condition has a direct relativity to the spending power of the western grain growers," he added. "When they commence to buy, the wheels of industry commence turning. All indications point to the crop being a bumper one. That means the grain growers will have money and when they have money they will spend it for the implements and other supplies they need."

Mining authorities of the east are paying considerable attention to the possibilities contained in the old Empress gold mine at Jackfish. Sir Stafford Brunton, of the Canadian Pacific railway mining department, Montreal, is making an inspection of the property, in company with T. Ballantyne, divisional superintendent of the railway at Schreiber.

NEW CONCERN OPENS



The Taylor Instrument Co. of Rochester, N. Y., have just completed negotiations for the purchase of the property at 110-112, Church St., Toronto, which has been known as the "Stevenson" Bldg., and which will be renamed the "Tycos" Bldg. Extension of manufacturing facilities will take place slowly as demand arises. Operations will commence on the repairing of all of the various instruments made by this firm, and assembling activities will be increased as occasion demands. The number of employees engaged will be added to as business increases.

DIE HEADS THAT SHOULDER THE WORK

One simple way to reduce production costs is to increase production. More and more shops are becoming 100% Geometric in their tool equipment, because they know that increased production invariably follows where Geometric Tools are used.

A Screw Thread Geometrically cut is correctly produced.

Geometric Die Heads can be fitted with Chasers for cutting close to a shoulder when required.

This Geometric Die Head is arranged for the Potter & Johnston Automatics. Note the Floating Shank, which makes close Camming unnecessary and also prevents inaccuracies caused by either forcing or holding back the Turret.

When you put a Geometric Die Head or Collapsing Tap on your Screw Machine or Turret Lathe, you put the name of the Geometric Tool Company there, and thereafter **they have a record to keep with you.**

Send in Your Specifications and Let Us Match Them With a Die Head That is Right.

The Geometric Tool Company

New Haven, Connecticut, U.S.A.

Grey Iron Castings

Light and Medium-Bench and Floor Repetition Castings; Capacity 15 tons per day.
Expert Metal and Wood Pattern Work. Our advice and estimates will save you money.
Semi-finishing operations on Lathe or Grill on Castings supplied if required.
ASK US.
THE KATIE FOUNDRY, GALT, ONT.

$67.60 Per Year

How much time in a year do you spend soliciting business for your shop? Half an hour a day? All right! Half an hour at a 6-day week comes to 3 hours a week. 3 hours a week at 52 weeks in a year amounts to 156 hours a year.

How much is your time worth—$2.00 an hour? To make sure we'll say $1.00.

That means you spend $156.00 worth of your time each year looking for business. This page is read and considered valuable by the majority of plant superintendents, purchasing agents and managers, both large and small, all over this Dominion. A one-inch card every week with a REAL message in it will do more for you than you can do for yourself. We only charge one-half of what it would cost your business if you were to use your own time.

	Per year	
RATES:— 1 insertion $1.50	$ 1.50	[ ]
26 insertions $1.40 each (every other week)	36.40	[ ]
52 insertions $1.30 each (every week)	67.60	[ ]

Put a cross alongside the space you want to use. Attach your advertisement to it and send it in to us.

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

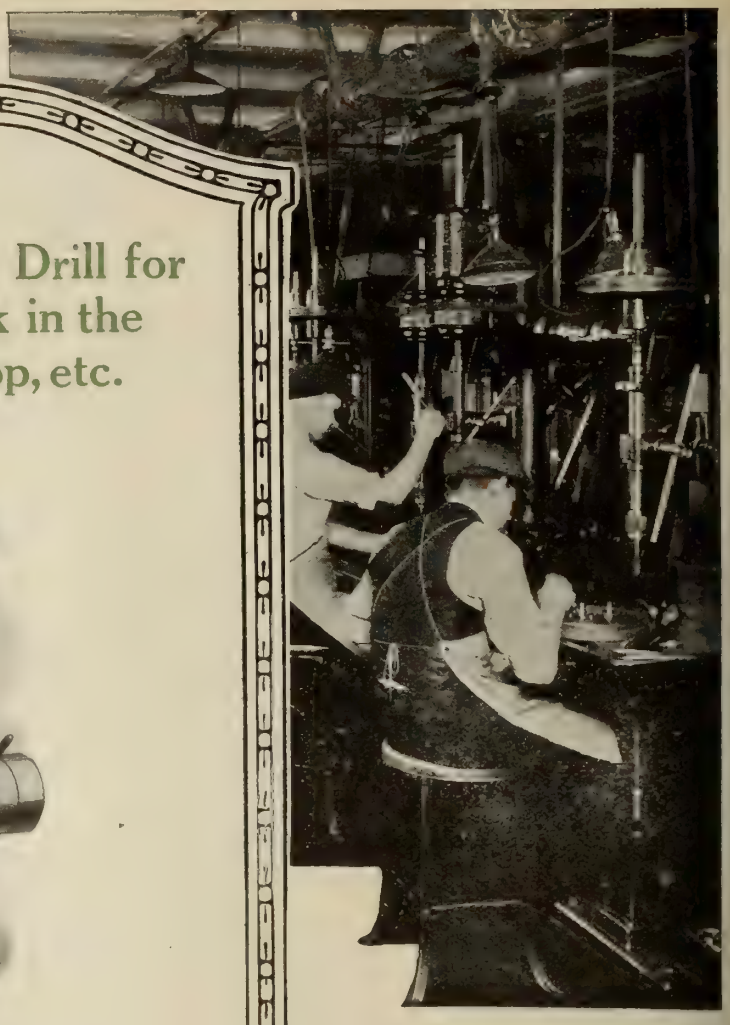
The Highest Grade Machinery and Supplies

The leading manufacturers of each line of machinery and machine supplies are represented by Canadian Fairbanks-Morse.

To buy from the nearest Fairbanks-Morse branch is to be assured of the dependable quality that is invariably associated with such well known products

Here Are Some of the well-known Lines we Handle:

Fairbanks Valves
Brown & Sharpe Machine Tools
McDougall Lathes
Gisholt Turret Lathes
South Bend Engine Lathes
Landis Threaders
Graton & Knight Leather Belting
Yale Chain Hoists
Esterbrook-Allcard High-Speed Drills
Norton Grinding Wheels
Dick's Balata Belting
Fairbanks-Morse Motors
Durabla Packing



And Fairbanks-Morse products are themselves second to none in quality—each one has built up a reputation for reliability.

The Canadian Fairbanks-Morse catalog is a dependable buying guide because it lists machines and machine supplies—for every requirement—made by the world's foremost manufacturers.

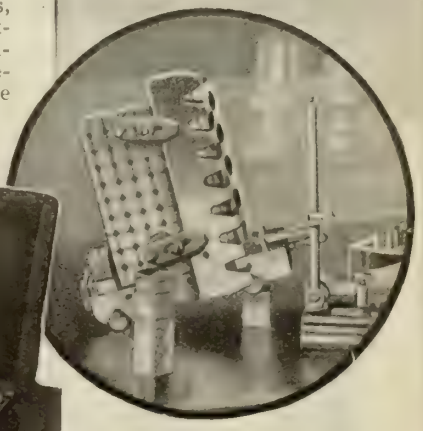
Laboratory Accuracy at a Toolroom Price

A TRIAL of Hoke Gages under your own conditions will convince you that our claims for these blocks are justified. You take no risk —the Pratt & Whitney guarantee is broad enough to assure satisfaction. The price permits the use of Hoke Blocks in every-day toolroom work. A reference set laid away in the safe is not earning for you what it should.



The Story of Hoke Gages—

A Booklet that will Interest You

Using a stack of Hoke Gages for checking profile on a Maag Gear Cutter.

This interesting catalogue will be sent on request to Manufacturers, Superintendents, Engineers, Inspectors, Tool or Production Foremen, and others who want to KNOW. It contains information covering — Gage Blocks, Registered and Identified; Means of Identification; Guaranteed Reliability; Advantages of Square Design; Reason for the "Hole"; Various Combination Sets; Attachments and How to Use Them; Some Every-day Applications — Testing Tapers, Scribing Lay-outs, Checking Profiles, etc.; Toolmaker's Flats; Mike-checks; Swedish Type Gages.

Details, prices — all the information you want — are yours for the asking.

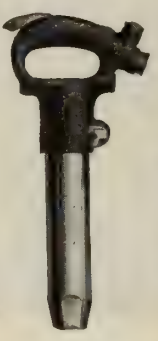
Cleveland Sand Rammers

FOR FLOOR, BENCH, PEIN AND FLASK RAMMING

Cleveland Sand Rammers are made in several sizes and weights, and are adapted for all kinds of Foundry Ramming.



The Piston Rods are packed with a resilient packing which prevents any dirt from entering piston chamber and working parts—They are fitted with either Round or Flat Rod as required. Cleveland Rammers are light in weight, have high speed and practically no vibration, making them ideal foundry tools.

CLEVELAND CHIPPING HAMMERS

For Foundry Work. Are furnished in any required size or weight for grey iron or steel castings; they have high speed, and are adapted for fast chipping now required by piece-workers.

CLECO PRESSURE-SEATED AIR VALVES AND BOWES AIR HOSE COUPLINGS

Are Standard Equipment Everywhere

Both Valves and Couplings are pressure tight.

Bowes Couplings are instantly connected or disconnected.

Bowes Couplings are absolutely air tight under all pressures.

Above cut shows the Never-Slip Clamp attached to Bowes Coupling.

IN STOCK:—RIVETING HAMMERS, DRILLS, REAMING, TAPPING AND FLUE-ROLLING MACHINES. CORNER DRILLS, PORTABLE AND BENCH GRINDERS, PRESSURE-SEATED AIR VALVES, ETC.

New Starrett Depth Gage has 1-inch Screw movement

A recent addition to the Starrett line of fine precision tools is this No. 440 Micrometer Depth Gage—especially designed for machinists who prefer or whose work demands a depth gage having a 1-inch movement of the screw.

Included with this gage is a set of three measuring rods by use of which the gage is capable of accurately measuring holes, projections, etc., of any depth up to three inches by thousandths of an inch.

In convenience and positiveness of adjustment, in perfection of finish, and in the thorough practicality and durability of every detail of design, material and construction, this new No. 440 Micrometer Depth Gage will be found in every way fully up to Starrett standards of quality, and a tool completely satisfactory to the most exacting mechanics.

Fully described and illustrated, with other new tools, in the new Supplement to Starrett Catalog No. 223 Write for free copies of this Catalog and the new Supplement.

ARMSTRONG
Threading Tools

ENSURE PERFECT WORK

A THREADING TOOL is essentially a Forming Tool and any error or inaccuracy in shape or angle in the tool point will surely be reproduced in the thread which it cuts and must result in poor fitting work. The cutters used in this Armstrong Threading Tool require grinding **on the top edge only** to sharpen, and therefore always remain true to form and of correct angle. Its use thus ensures perfect fitting threads, saves much grinding, and also dispenses entirely with forging and tempering. Furnished with either High Speed or Carbon Steel cutters.

Catalogue on request.

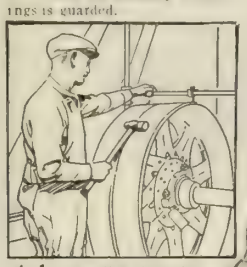
AMERICAN STEEL SPLIT PULLEYS



1st Careful laboratory work watches the fitness of the steel itself.

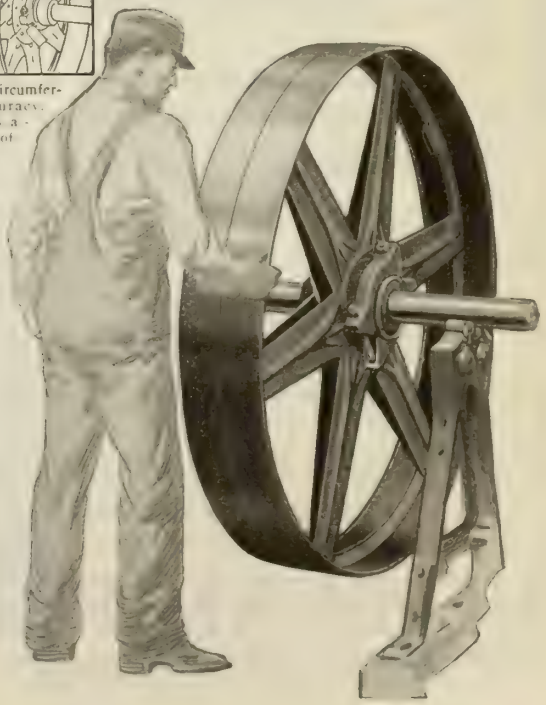
2d The micrometer faithfully guards the uniform correctness of jigs, dies and tools.

3d This test picture shows how the accuracy of bushings is guarded.

4th Guarding circumferential accuracy. Lasting trueness is assured by a series of such tests.

Uniformity of Service

THIS essential condition of pulley efficiency is safeguarded by a long series of scientific and practical tests in the manufacturing process of "American" Pulleys. These tests make certain that each "American" Pulley is as true and perfect as every other "American."



And, in turn, this assured uniformity must be one of the major reasons why nearly six million "American" Pulleys are now in operation, both here and abroad.

A book entitled "Getting Maximum Pulley Efficiency" will be mailed you on request, at once.

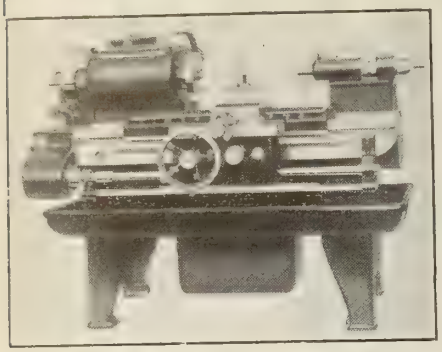
Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy



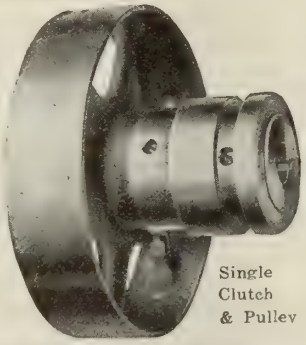
And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

The Walton Co.
Hartford, Conn.

THE JOHNSON FRICTION CLUTCH
AS USED ON THE
"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch.

The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy: The Rockford Tool Co., Rockford Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

The Lion and The Mouse

DO YOU remember reading in the school books about the great big lion who was caught and trapped in a gigantic net by hunters? Then along came the little teeney mouse who nibbled away at the netting and was successful in setting the lion at liberty again. The net was too strong for the lion to break but the constant nibbling of the mouse, breaking mesh after mesh, was able to perform the seemingly impossible.

A person who is not subscribing to CANADIAN MACHINERY is in exactly the same circumstances as the lion imprisoned in a corner—not being able to enjoy the freedom of expanding his capacity for knowledge.

CANADIAN MACHINERY acts as the mouse. Week by week it will give information—which, on account of the lack of it, has tied you up in an industrial way—will nibble away the meshes, one at a time, that are keeping you from getting the results you want.

Ask us to send you a sample copy. It will not obligate you and it will be a pleasure to us.

CANADIAN MACHINERY,
143 University Ave.,
Toronto, Canada.

Please send me a sample copy of your paper and oblige.

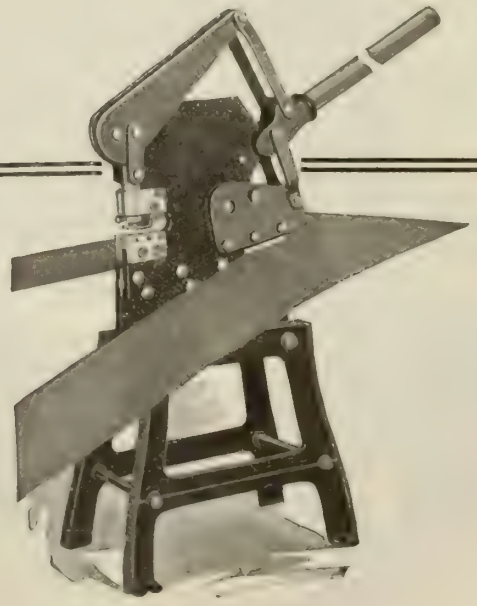
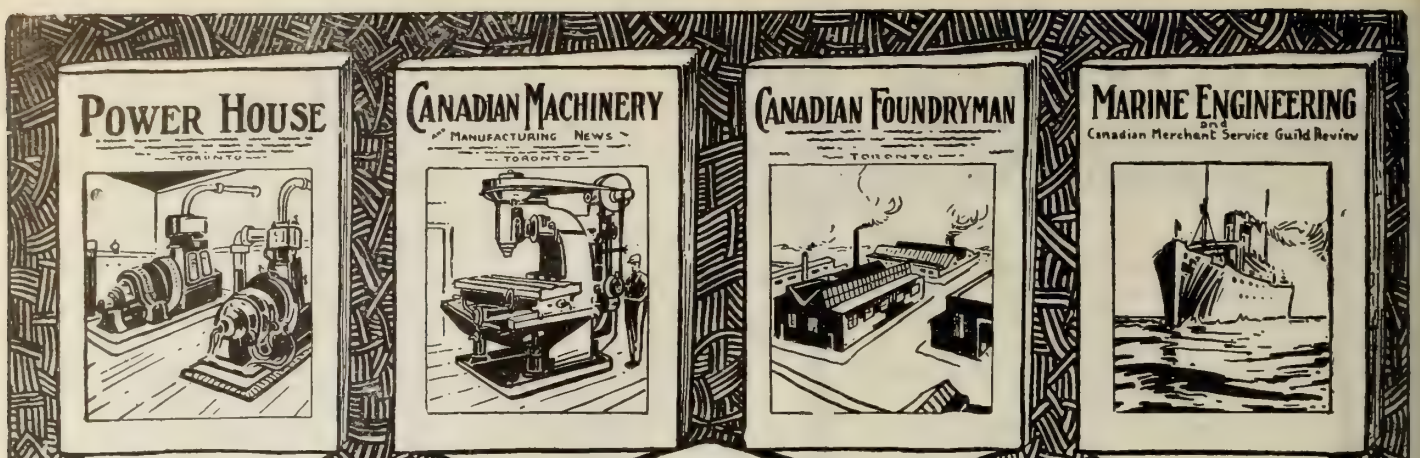
"CANADIAN"
HAND POWER PUNCHES AND SHEARS

All Canadian hand power punches and Shears are made with "Armor Plate" frames.



This frame construction consists of a rolled steel plate having a tensile strength 7½ times that of cast iron. This strength permits of a machine much lighter and more compact than is possible with either cast iron or cast steel.



Let us know your punching and shearing requirements. We have an "Armor Plate" machine for the service. Remember our Armor Plate line comprises power operated machines as well as hand power.

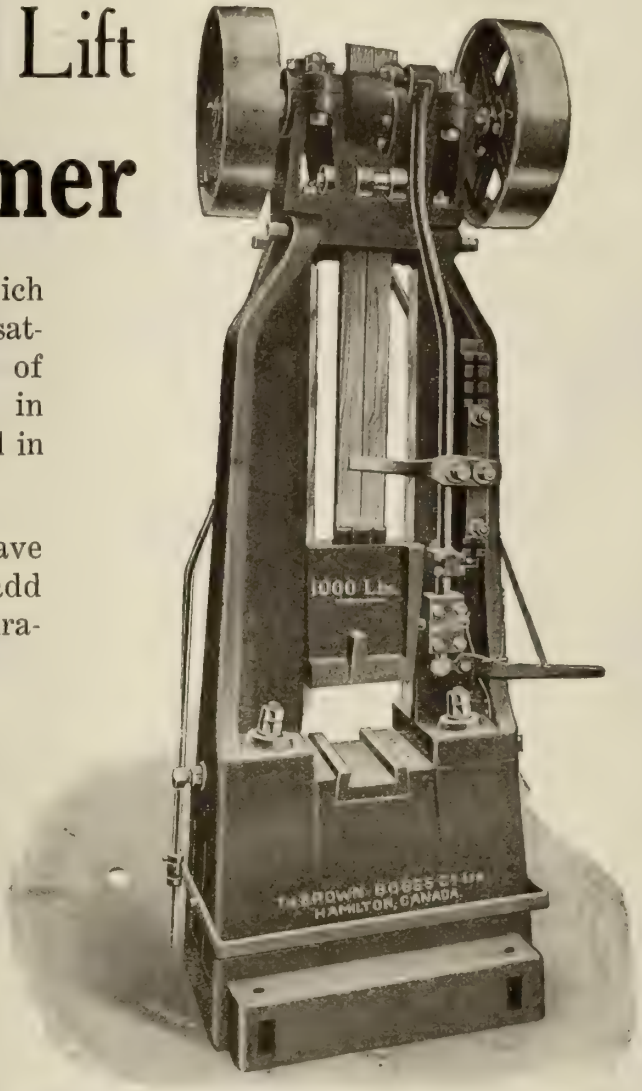
Thirty years' experience and dozens of practical men in your own line, stand ready to serve you. Let them! Subscribe for your paper to-day.

Men with selling problems will find a profitable tip in the statement made by a prominent manufacturer recently, "I use MacLean Publications because I am satisfied that papers with such a high standard of editorial excellence, MUST have an influential following."

BROWN-BOGGS

B B

1000 lb. Board Lift



Drop Hammer

It pays to choose machinery which has a reputation for giving long, satisfactory service. The excellence of Brown-Boggs products is shown in the results which every "B-B" tool in use is attaining.

The latest type "B-B" hammers have many exclusive features which add greatly to their efficiency and durability.

The old-fashioned, noisy gears have been eliminated entirely, the hammer being lifted by friction exerted by a powerful eccentric motion under perfect control of the operator at all times.

On all the sheet metal working machinery, presses, shears, rolls, etc., which you buy, make sure of the Brown-Boggs trade mark—it means **reliable service!**

McDougall

Built in 16 in., 20 in. and 24 in. Sizes

A Name that Stands for All that is best in Machine Tools

McDougall Shapers are well-known for their perfection in design and build. This reputation has been achieved by actual operations in various shops under all kinds of working conditions. McDougall Shapers "make good" because they are easy to operate, have great strength and produce work accurately and fast. Made in 16, 20 and 24-inch sizes. Complete description promptly furnished.

The R. McDougall Company
Limited,
Galt, Ontario.

Accuracy of Form
Duplication of Accuracy
Increased Production

—three of the outstanding features of the new

BROWN & SHARPE GROUND-FORM GEAR CUTTERS

from 1¾ to 12 pitch inclusive

ACCURACY of form—the primary requirement in precision gear cutting—is assured by the grinding of the tooth form—correcting all hardening distortions.

DUPLICATION of accuracy in different cutters through this positive control of form gives the user of cutters further ability to duplicate this accuracy in the finished gears—this continued accuracy and uniformity which makers of gears strive to maintain.

INCREASED production, due to the freer cutting action and keener cutting edges of these cutters, has been proved by actual tests to be surprisingly great. The freer cutting action, which is largely responsible for this increased production, is due to each tooth doing its share of the cutting, for the grinding of the form has so corrected any hardening distortions that no single tooth or group of teeth can do the major part of the work—each must do its share. Consequently the finish is correspondingly improved and cutter wear greatly reduced.

As to cost, these ground-form cutters necessarily list somewhat higher than those with the unground form but their ability to produce more and better gears per sharpening of the cutter will affect a pronounced saving in ultimate cutter cost—they mean high cutter economy from all angles, both as to quality and quantity of the gears produced.

Overcoming Heavy Costs of Belt Maintenance

Transmission Problems Should be in Charge of Competent Man —Inspection Should be Made Regularly—Importance of Proper Alignment—Lacing of Joints Should Be Carefully Performed

By J. H. RODGERS

ECONOMICAL production under modern competitive conditions is largely a matter of getting the most out of plant and equipment. Machinery, tools and appliances are for the most part carefully purchased and industriously kept in good working order after installation, yet in mills where the greatest care is exercised in the constant maintenance of machinery, little or no attention is paid to the upkeep of transmission belting. The result is a loss in power and production so serious that it frequently causes a very appreciable loss in profits. Satisfactory operation of any system of mechanical power transmission depends upon the care with which the belting equipment is selected and cared for after installation. Yet so general is the efficiency in most mills that the extent of loss in production through this item is seldom realized.

Saving Wasted Power

The power that is produced is that actually delivered to the machine pulley—and the power that is costly is that which is lost somewhere between the boiler and the belt on the driven pulley. Much of this wasted power can easily be saved by constant, careful attention to the upkeep of the transmission system. A good share of power loss is caused by neglecting to keep belting in first-class condition; by failure to tighten loose belts, to dress dry belts and to repair worn-out belts. Part of this failure is due to the fact that the loss is not often recognized by mill superintendents and master mechanics. The greater part, however, is due to the fact that anyone in the average mill looks after the belts on his own machine or in his own room.

Supervision of Belting

No one would think of running a mill without a competent man to take charge of and repair machinery. Why then expect the belting on which those same machines are directly dependent to operate with little or no skilled attention? The first move to cut down transmission costs, reduce power losses and eliminate break-downs should be the placing of one man (on each shift, if necessary) in complete charge of all transmission equipment—shafting, pulleys, hangers and belting. Put him in absolute control and hold him to the responsibility. Allow no installation changes, repairs, or dressings except by him or under his direction. This arrangement is advisable for two reasons. First it insures the equipment of constant attention so that repairs are made when needed and not two weeks later as is often the case. A stitch in time is particularly true in the case of belting. Then second, it ensures, so far as may be, uniform treatment of the belting—a very desirable factor in increasing belt-life and in lessening the chances of breakdowns and lost production.

Experienced Supervisors Necessary

When possible, it is desirable to put an experienced man on the job, but where this is impossible, a man should be selected and given a short course of training in a belt factory, where he will learn how to make laps, take up belts, repair and dress belts, etc. A week or ten days in any good belt shop will go a great way toward transmission efficiency in the mill. Most belt manufacturers are glad to allow a man to spend this time in the factory, learning the rudiments of belt making. A mill should be provided with the necessary equipment for doing all ordinary

This article was prepared from material supplied by the Saddler and Haworth Co. and the experience of the author.

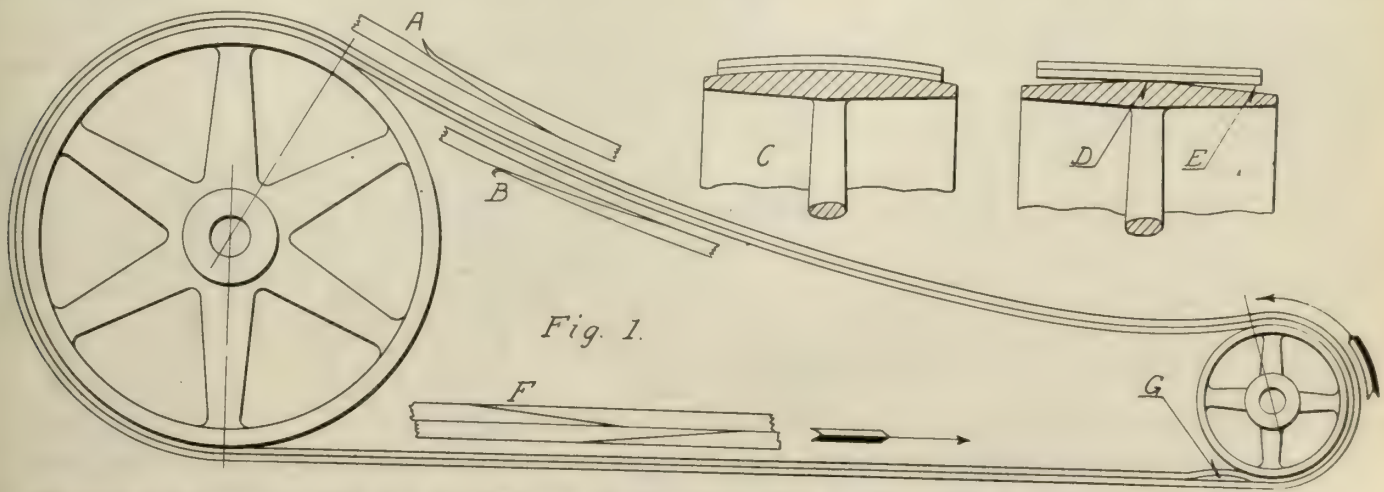

Fig. 1.

Fig. 1.—A, thin edge of lap curling from air pressure. B, curl from pulley contact. C, proper method of crowning pulley. D, avoid sharp crown. G, ply lifting due to creep.

belt work—breakdowns and tie-ups are too frequent and too expensive to depend on outside repairs. The tools ordinarily required are clamps and rods (for holding belt when cementing endless), belt scraper, belt shave, slicker, spoke shave, hand punch (for lacing holes), cement, brush, and kettle for melting the glue. These tools can be supplied for a reasonable amount from any mill supply dealer or belt manufacturer.

Regular Inspections Needed

After placing your belt man in charge, see that he makes a regular inspection of every belt in the mill at least every two weeks. This systematic inspection should cover such points as general conditions of belt, need of dressing or of cleaning, tension, condition of laps and joints, amount of belt slip, amount of wear, etc. Pulleys and shafting should be carefully watched to see that they are in strict alignment. In many mills it has been the practice to have regular reports made of such inspection—but this does not always pay, except in the case of large mills with hundreds of drives. Experience has proved that constant, systematic inspection of all shafts, belts and pulleys, by a competent man, followed up by prompt attention to all necessary repairs, will reduce belting bills from 10 to 20 per cent. while practically eliminating any unexpected delay through faulty power transmission. All trouble with the belting in the plant should be immediately reported to the belt man, and he should be held responsible for the continuous operations of every machine in the mill.

The second point in economical operation of a power transmission system is the standardization of belting for each drive. This merely means that for every drive there is one type, brand, ply, width and weight that will work out most efficiently. Find out as nearly as possible what that belt is—and order it for that drive when necessary. The standardizing if applied with a fair measure of common sense and not carried to extremes, will amply repay the time and effort on it.

Belting should be purchased with the due regard to the mechanical and physical condition of the drive. The main things to keep in mind when ordering belting are; diameters, faces and speeds of pulleys, type of drive (open, crossed, vertical, etc.,) centre distance between pulleys, load to be carried, and the atmospheric conditions (dust, steam, fumes, etc). Pulley diameters control the weight or thickness of the belt to be used; belt speed controls the power that can be transmitted by the belt; load to be carried determines belt width; type of drive and physical condition determine the type of belting best suited.

Nor is it always necessary to specify first-quality belting of any particular type. Where the work is light or the pulley large or the speed low, second quality belt can often be used with just as satisfactory results as higher priced brands. When the best type, ply, width and weight for any drive have been determined by the belt man, make a record of it for the use of the purchasing department or for the superintendent. Always specify the standard instead of "using what you have left over" from other work—it pays better.

Proper Tension

The third item to watch out for is belt tension. The tightness with which belts are put on pulleys is of prime importance. If a belt is too tight, there is a large loss of power from excessive friction at the bearings, to say nothing of the fact that the belt itself is overstrained and weakened. On the other hand, if a belt is too loose, it is liable to flop around and jump from the pulley, particularly when working where a load is suddenly thrown on or off. If too loose, there is sure to be unnecessary slip and loss of power as well. When belts are installed and taken care of by one man, the errors of too tight and too slack belting should be avoided and a uniformity of tension will result, which could not be secured as easily in any other way.

Aligning Shafts and Pulleys

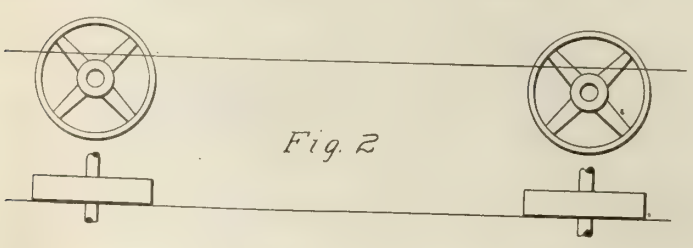

Fig. 2 shows a simple method of lining up two pulleys. The operator, with a helper, takes a piece of cord and stretches it from the outside edges of the two pulleys just above the shaft or hubs if the latter extend beyond the edge. With this method it is understood that the shafts have been lined up previously and that the pulleys run true. When using the string it is well to try the pulley in several positions to allow for any irregularity in run of the pulley.

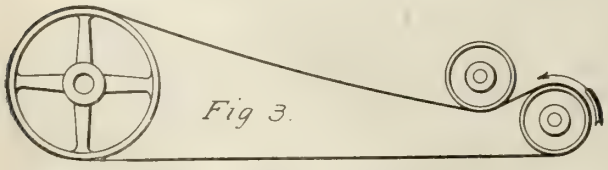

Crowning of Pulleys Important

Steady running of belt is essential to effective transmission. For continuous drives, belts are generally run on pulleys that are very little wider than the belt, and to maintain its position in the centre, the pulleys are invariably crowned. This crowning usually consists of two straight tapers meeting at the centre of the pulley face. The amount of the taper varies from ⅛ to ¼ inch per foot; that is, a pulley 12 inches wide would be about 1-16 inch larger in diameter in the centre than it would be at either edge. In a straight taper crown, however, it will be seen that the apex D, Fig. 1, forms a definite or pronounced breaking point; nothing very serious possibly, but with a tendency, especially in new and heavy belts, to provide an air space at the edges E. A better plan of pulley crowning is that shown at C, where the surface forms an arc; this method equalizes the bending stresses throughout the width of the belt and makes the surface contact more uniform.

Preparing Belt For Lacing

One of the essential factors of a belt joint is that the ends should be perfectly square with the run of the belt, to assure its smooth running. When cutting a belt the use of a try square, as shown at A, Fig. 7, is always advisable. Without such a tool the tendency is to make an angular cut as at the right, so that when the joint is made it has the appearance as illustrated at B. When passing over a pulley the belt develops a tendency to oscillate, and such a condition is very much aggravated when the belt is running a little loose. To prevent it jumping off, a stick is frequently secured to some rigid support and extended down at the side of the pulley.

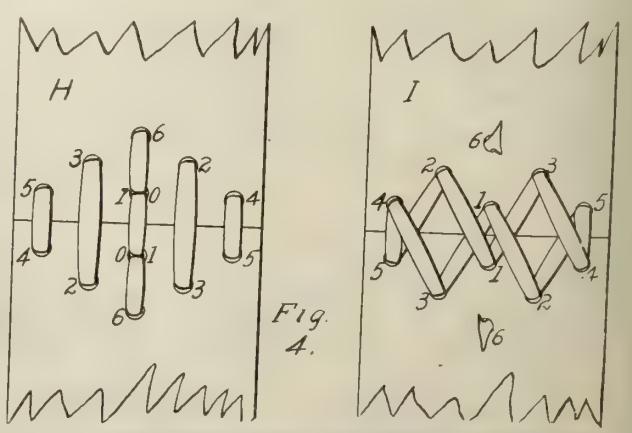

Fig. 2.—Aligning pulleys with string. Fig. 3.—Position of idler. Fig. 4.—Showing effective method of lacing belt, straight lacing on pulley side.

This, however, provides only a temporary remedy for a previous fault, as the weakest portion of the belt—the laced joint—is continually brought into violent contact with this "guide" and eventually the efficiency of the drive is destroyed.

Making a Laced Joint

In making a joint it is advisable to use a thin lace in preference to a thick one. This coincides with what has been said on belt contact, as it is clear that the thicker a lace is the less will the contact be when the joint is passing around the pulley, and in addition the jar will be all the more pronounced. When making a joint the straight lacing should be made on the pulley side. Owing to the different widths of belts no fixed rule can be applied for lacing, but in general the method may be the same for every case. Holes should not be closer to the edge or end than one-half inch, with centre holes spaced accordingly. The best practice is to commence at the centre and work out and back on each side. As a guide the illustration Fig. 4 is given. Starting at 0 and 1 the order is as follows: 2, 3, 4, 5, 4, 3, 2, 1 or 0, both sides of the centre being identical; the locking is performed by passing the free end through a small hole 6, and cutting a short slit to form a hook that will prevent the lace from coming out. This lock should be on the outside of the belt. After the joint is made it may be lightly hammered down with a wooden mallet.

Use Small Lace Holes

It must not be taken for granted, however, that all one has to do is to cut off a piece, punch a few holes and secure again with a lace, to obtain an effective drive. The fundamental details of a properly made joint may often seem of little import, but the subsequent operation of the belt may depend, very

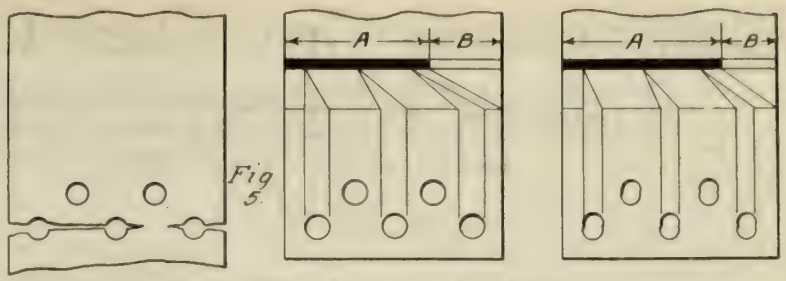

Fig. 5.—Effect of having lace holes too large.

largely on the consideration given to these apparently insignificant matters. When making a repair to a belt the beginner will usually make the lace holes of large size as indicated at centre of Fig. 5. The inevitable consequence of such practice will be that shown below at the left. With very few exceptions, a belt will tear across the lace holes and seldom will fail in a direction parallel to the belt length. For this reason it is imperative that the amount of the leather cut be kept as low as possible, consistent with the size of the belt and the thickness and width of the lace. Where it is necessary to enlarge the holes it should be done as shown at the right. This is obvious when comparing the resultant efficiency of the belt in each case. The short light space indicates the portion of the width cut away by the holes and the dark portion the effective section of the belt.

The best side of the belt to run upon the pulley appears to be a debatable question, as many favor the hair or smooth side, while others prefer the reverse. However, as the efficiency of a belt drive relies on the frictional contact between the surfaces it would seem practical that the smooth side would have the preference. Another factor in its favor is that of the recognized fact that the portion of the belt best suited for tensile strength is near the flesh or rough side, and the hardest side best adapted for the compression action; these features being quite evident when belts are operating on small pulleys.

It is evident that the slacker a belt can be run, up to a certain point, and do its work satisfactorily, the greater the economy. In installing belting and in taking it up, consideration must be given to the fact that certain kinds of belting are affected by atmospheric conditions, lengthening and shortening according to the amounts of moisture in the air. Water-proof leather belting, properly made, does not stretch much even when working in most air for a long period. The best tension at which to operate a belt is that at which the belt will carry its load easily without straining and with a minimum of journal friction. Operate all belts just as slack as possible without slipping. When it is necessary to operate a leather belt tight on a drive to carry the load, that is a sure indication that there is something wrong with the drive which should be investigated and remedied.

High Tension

With an intermittent load, or one which varies greatly, it may be necessary to instal and operate belts at high tension. Bearings and shafting of course play a part in the amount of tension which can economically be used. For example, a belt can be installed with a greater tension on a self-aligning bearing than on a rigid pillow-block bearing. Again, a belt can be installed at a greater tension of a 23/16 in. shaft than on a 15/16 in. shaft. Belts which operate under a heavy load or which are travelling at high speed, usually require taking up every six months or so. Failure to do this means great waste of power through belt slip. When a belt runs suddenly to one side, after running straight for some time, it may be laid to sudden overload, or belt too loose. It may be necessary to reduce the load and tighten the belt. Where the required tension cannot be secured normally, idlers are used, both to increase the arc of contact, and to increase the tension. See Fig. 3.

Fourth: Eliminate injurious dressings and use a little good dressing sparingly. This is perhaps the most neglected item in the care of belting—and one of the most important. Belt dressing is necessary either when a belt is slipping badly for no apparent reason or when in the case of leather belting the natural oils have dried out of the leather, leaving the belt dry and harsh.

(To be continued)

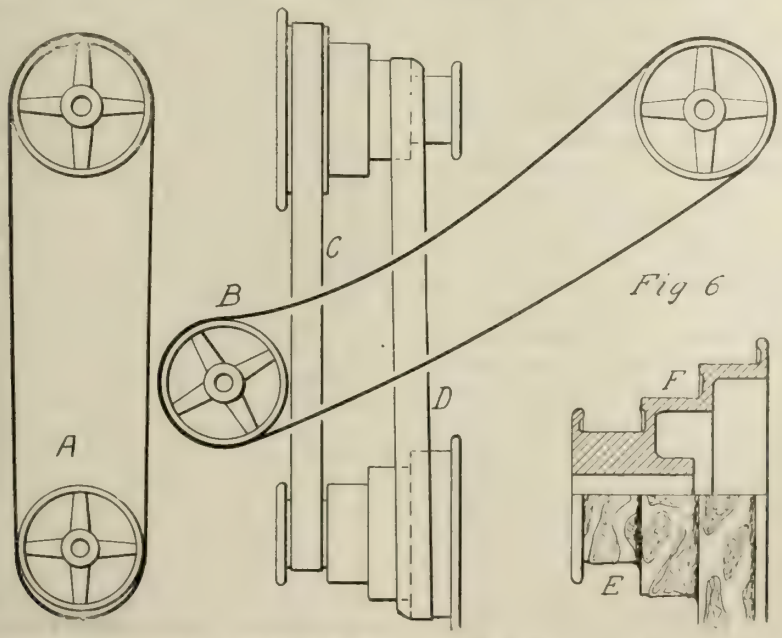

Fig. 6.—Vertical belts must be kept tight. D shows a serious fault on cone drive. E shows abnormal use of belt dressing.

Manufacturers Give Their Views on New Tax

Consensus of Opinion Seems to Be Sales Tax Will Not Make Much Difference—Stamp Tax is Not in Favor—One Plant Owner Does Not Like Value Basing of German Money.

"WE DO NOT BELIEVE the tariff sales tax will make much difference to our business," writes George A. True, president of Northern Crane Works, Walkerville, Ont. He continues: "We think all of us here are much in favor of the sales tax, as compared with the profits tax. The taxes have to be raised some way and it seems to us that the sales tax, if intelligently levied, is the best possible tax. We do not believe it will interfere with Canadian business at all, nor do we think it will cause an increase in importations compting with the Canadian manufacturers.

"We cannot say so much about the proposed stamp tax. We think it is unwise in the first place to increase the stamp tax and we think the method of levying it is open to decided criticism. There should be a reasonable limit and we cannot see the consistency of increasing this tax and applying it in a manner in which it is proposed to apply, especially to transfers of stocks, shares, etc.

"The exchange of these securities is just as legitimate in a line of business as exchange of material or commodities. There is perhaps justification for some reasonable stamp tax thereon, but as drawn we think you will find with its practice a great many absurdities. We have not forgotten the fiasco in reference to the 'marking act' put into effect last year. We predict there will have to be similar 'modifications' in the stamp act."

A. T. Enlow, president of the Dominion Sheet Metal Corporation, Hamilton, says: "The change will, of course, affect our business as every other business, but in our estimation it is fair and equitable and while a good portion of it will be passed on to the consumer, we as consumers will also stand our share and we do not believe that Canada will ever struggle out from under her war debt unless all contribute in fair proportion to the payment thereof.

"In our estimation there is no better way of reaching all the people in proportion to their means and their purchases than by a sales tax, and while we are not enthusiastic about any kind of a tax, we have not been able to conceive of any plan which would be in the end less injurious or more beneficial. It is true that certain classes as producers properly receive exemption, and we believe that there is no reason why as consumers they should hesitate to pay their share of the tax burden.

"Not only in this connection but throughout the whole budget, we believe that the Minister of Finance has been prompted by not only good motives but wise experience, and from our viewpoint good times which are coming back will not be impeded in the least."

"We cannot say at the moment that the new sales tax will have any striking effect on our business," says P. H. Cooke, sales engineer for the Norton Co. of Canada, Hamilton, Ont. "While it is a law which will increase the cost of our commodity to our customers by the amount of increase of the tax," continues Mr. Cooke, "at the same time it is a law which will affect our customers in selling their own commodities. Once understood and correctly interpreted by everybody, we do not see that in itself there will be any tendency to add or subtract from our sales volume.

"We find, however, that there are several interpretations of the law. The thing most desired is to understand it properly and apply it as it is intended. In this way there should be no cause for any difficulty."

A. J. Oliver, secretary and manager for the R. M. McDougall Co., Galt, says:

"We cannot see why the new sales tax will make any material difference in business. It appears to us," he continues, "that this way of raising money is just about the easiest way that the government could take. The only thing that we could see would be better would be a general sales tax which would require to be as heavy as the present excise tax. The money has got to be raised, and with the sales tax we all help to pay it and it is certainly a very simple tax to collect for if a person does not pay to-day they are liable to do so the day after to-morrow, as no doubt auditors put in periodical appearances."

F. E. Mutton of the International Business Machines Co., Toronto, takes a different view of the matter. He says: "One outstanding feature in the recent budget is the government's apparent decision to allow German goods into Canada, basing the duty value on the present market value of German money. This to the writer is a very serious situation. It means that the duty value of the German imports would be less than half of the factory cost of the article, for the reason that the German mark at present is worth about only one third of a cent and if the government do not change their attitude it must certainly mean the putting out of business of many important industries in this country. We, of course, do not know at present writing just how serious this would be to us, but it could become very serious."

F. J. Lavery of Brown Boggs Co., Hamilton, states: "It is a little early yet to say just how the sales tax will work out as there is some indecision on the part of the manufacturers regarding same. It will take a little while to know where we are at," continues Mr. Lavery, "but, of course, on the whole, it is the same old story, that the consumer has to pay the piper. The country has got to have revenue, and apparently this is about as easy a way of distributing it among us all, as any they can devise. We do not think the extra amount of tax is going to have any bad effect on business in general, as the small addition will not deter any one from buying, who actually requires the goods, and with the outlook for a good crop this year, the Canadian people are becoming a little more optimistic."

"There is no sales tax on either raw sugar coming into Canada being sold to us, or on sales made by us of refined sugar," says John D. Lowry, of the Atlantic Sugar Refineries, Montreal.

"There is however, an increase in the tax on certain supplies used by us, such as bags, etc., and this will tend to make it a little more expensive for us to turn out our finished product," concludes Mr. Lowry.

"In the writer's opinion," says T. P. Howard, of the Howard Smith Paper Mills, "the new tariff sales tax will not make very much difference, as we simply have to pass it on to our customers and will, undoubtedly, be handed down until eventually it is paid by the consumer as is the case in all such taxes. We do think, however, that the stamp tax on cheques should be on a flat basis; that is for example—3c on all cheques up to $100.00 and a sufficient tax above to realize the necessary revenue."

"We have had quite a number of complaints from our customers on the new sales tax," remarks E. M. Jones, general sales manager for W. H. Banfield and Sons, Toronto, "and there seems to be a feeling that the manufacturer should reduce his price in order to compensate the middle-man for the tax. On some of our lines we have a certain resale price and we intend to increase the resale so as to be able to compensate the middleman for the difference. On some of our lines, unfortunately, we cannot do this. The situation is so new that we have hardly anything we can say on the subject at this time."

A. E. La Belle, vice president of the St. Lawrence Flour Mills, says: "I have personally been right along in favor of a sales tax which is the most equitable way of reaching everybody. We know that we have a heavy debt to pay and by a sales tax, those that buy much pay more, and those who buy little pay less."

C. W. Sherman, president of the Dominion Foundries and Steel Co., Hamilton, Ont., says that they rather favor the sales tax as a means of getting revenue for the government. It is a mat-

(Continued on next page)

How Do You Issue Drawings to the Plant

Conditions Will Determine the Most Effective Method—Choice of the Detail or Assembly Drawing—Single Operation Sheet Has Many Good Points—Use of Data Cards

By HUBERT BENTLEY, A.M.I., Mech.E.

AT ONE time or another, the question of "the best method of issuing drawings to the works?" has no doubt been asked in the majority of engineering works, both large and small. The answer depends on a variety of circumstances. Unfortunately the efforts of the drawing office to introduce a new system are too frequently turned down, while expenditure on works equipment is on a lavish scale. Where the question of reducing production costs has been seriously considered and where in recent years specialized quantity production has been the basis of manufacture, the issue of the necessary drawings to the works has come in for more consideration and deservedly so. Up-to-date methods in the issue of the works drawings are essential to success in both drawing office and the works. While the majority of firms nowadays issue drawings in some form or other to their workmen, very frequently, these are of such a nature as to cause a serious waste of time in seeking explanations and additional information. Many firms have adopted the single operation drawing which is described later, and its effectiveness for assisting successful manufacture has been repeated y proved.

Methods Usually Adopted

The three principal ways in which the drawing may be issued to the works may be described as (1) the assembled detail drawing, (2) the tabulated drawing, (3) the single-operation drawing. The first of these is the oldest and most common method, and the drawing is usually issued in the form of a blueprint or photoprint. It would comprise an assembled drawing of some unit of the machine—in the case of a milling machine, say, the gearbox or the table, and may give, in addition to two or three views of the assembled unit, one or two parts in separate detai ; but all on the same sheet, and fully dimensioned. The tabulated drawing has been adopted by many firms engaged on small repetition work. It comprises the drawing of a single detail which, while made in a range of sizes, does not differ in design. Instead of inserting figured dimensions in the drawing, letters are used, and a suitable table placed under the drawing gives the sizes corresponding to a given letter, and for each size of machine built. These tabulated drawings are generally in the form of blueprints or photoprints, and frequently mounted on cardboard, and being smaller than the assembled detail drawings, are much more convenient to handle. The single operation sheet, the latest innovation, is clearly a product of specialization. It gives the drawing of a separate detail, with just the necessary dimensions and information to enable the operator to produce speedily. The single operation sheets may also be issued as blueprints or photoprints, but more frequently these drawings are issued on cards convenient for filing.

Which is the Best?

The character of the work, of course, should be the deciding factor in choosing any of these methods. Where only one or two machines are to be produced at a time, or in the case of some special attachment that is being built, the assembled detail drawing would be the most economical. But when the parts are to be produced in bulk, the extra time spent in the preparation of either tabulated drawings or single operation drawings will be more than justified; the latter being the ideal arrangement, and the one which we are to describe more fully. While pointing to the large amount of time taken up in the preparation of the initial drawings for the single operation cards, those firms who have recently introduced same are more than satisfied with the smoothness of working that follows in the shop. The great advantage of the separate drawing is its tendency to minimise mistakes and time wasting. The workman has the information before him that he requires for turning out the job. He has not, as in the assembled drawing, to sort out the detail he is machining, with a consequent wait for the charge-hand to make something clear, nor has he even to read figures from the columns of a table, both of which methods are conducive to mistakes if the operator is not careful. Where a limit system is being worked, a separate drawing lends itself much better for the indication of the various degrees of finish required. The fact that separate drawing can be worked well in combination with a costing system is another point in its favour.

Specification Cards

In various works the writer has in mind, in which the machines are built on a quantity basis, these separate drawings, are issued on small white cards. The card has the following printed headings; type of machine, size of machine, operation, quantity required. The information required by these headings is filled in by hand. When issued to the works this card is enclosed in a transparent envelope, and each machine is provided with a conveniently placed stand for holding the card, and so preventing unnecessary handling. The sectional charge-hand gives out the card for the next job in good time, and when ready for commencing, the turner, planer, or whatever operator it may be, takes the card to the works office and receives a suitable time card, on which the clerk has filled in the printed information from the drawing card, as well as the name of operator and number of machine. A time recorder is employed for booking the time of commencing. On completion, both the cards would be taken to the works office and the time recorded on the time card. Suitable reference data is taken from the time card and re-entered on various cards in the works office, each colour of card indicating a type of machine manufactured, and facilitating quick reference. On handing in his cards for the completion of a job, the operator will also have his card for commencing the next.

While methods similar to this described, are in vogue in the large works, where quantity production is normally the usual routine, in the writer's belief, it has not yet been seriously considere by the vast array of medium-sized engineering works, whose stock orders may be no more than one or two dozen. That in such cases as these the separate drawing can be efficiently employed, and considerably assist output, there is no reason to doubt.

Editors Note:—As considerable cost is involved in this department of engineering work, we would like to have the opinions of those readers who have had experience of this nature. Mr. Bentley, as well as the questioner, would appreciate the views of other production engineers.

MANUFACTURERS' VIEWS ON NEW TAX

(Continued from previous page)

ter that we have not given a great deal of thought to but it seems that the government must have revenue and this spreads it out in an equitable way."

M. R. Meldrum, president of the Herbert Morris Crane and Hoist Co., Niagara Falls, remarks as follows: "So far as I can see this tax will apply equally to all people in our trade, and while it may have the general effect of discouraging fresh business to some slight extent, I do not see that it will hurt any individual manufacturer adversely. While constitutionally opposed to any form of tax, we must recognize that the affairs of the country are to be carried out, and to do this money must be raised.

"On the other hand, very serious objections are evident in connection with the tax on checks, and I hope that the government will be prevailed upon to withdraw this portion of their taxation proposals for the benefit of the trading community at large."

Steel For System, Safety and Sanitation

Metal Shelving, Cabinets, Racks and Other Furniture Being Used Extensively in Factory and Office—How This Equipment is Being Employed in Bertram Plant—Superior for Many Purposes.

By S. S. MOORE

"THE AGE of steel seems to have arrived," was the observation of a visitor while being "shown through" by the manager of a manufacturing plant. They were inspecting what appeared to be the storage and stockrooms. The racks, cabinets, desks and lockers were all of metal—or furniture steel all done in one color, and presenting an appearance that immediately suggested system, as well as cleanliness. "As far as we are concerned, it has arrived, and I will tell you why without saying a word," replied the manager, and he took from his wallet a newspaper clipping and handed it to the visitor. It read thus:

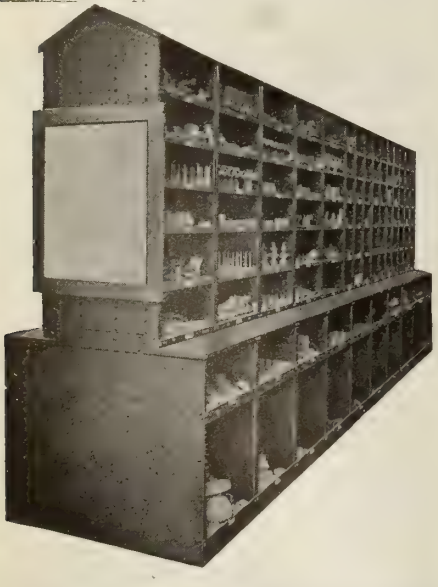
"A fire in the stockrooms of Blank and Blank, caused considerable damage, not so much to the building as to contents of storage racks and cabinets. There are conflicting theories as to the origin. It may have been caused by a match or a cigarette in a wastepaper basket, but the nightwatchman claims there was no evidence of fire when he passed through the room about one hour before. Wooden wall racks, containing stationery stock and advertising matter, were destroyed. The books of the main storeroom had fortunately been placed in a steel cabinet and escaped damage."

Fire Taught a Lesson

"There you have it," continued the manager. "You know, when that fire occurred, I was a member of the firm of Blank and Blank. Where the newspaper got the cigarette theory I don't know, because smoking, while not prohibited, was certainly not encouraged. However, there is no accounting for human frailty, and whatever the cause, the fire taught us several things that had no particular relation to fire risk.

"In the first place, those old wooden cabinets and other equipment such as desks and racks, had been there for years. They were ill-adapted to modern purposes. We found that in some respects they were used as catch-alls for all kinds of useless junk. They didn't look tidy, and they were no good when system was essential. To make a long story short that fire enabled us to go in for a housecleaning that had been long overdue. If you visit that warehouse today you will find steel, where once was wood. There are steel cabinets with adjustable shelves. These are built in sections, and are adaptable to any kind of system or space. Cabinets with doors contain more important documents, and this plan is also adapted for advertising matter. I have seen a whole publicity campaign laid out in one section of cabinet so regularly, and with such system, that the advertising man's secretary could operate the whole series in conjunction with their newspaper campaign.

Steel in Draughting Room



"Then, for blueprints, you will find the same arrangement there as here. A cabinet with a series of large flat drawers in which an index system may be employed. We have a draughting room in which the entire equipment is of steel—that is as much of it as can be. This steel equipment, racks, cabinets, desks, safes and tables presents to me, as compared with the old Blank and Blank equipment, all the difference that there is between a company of well-trained soldiers and a gang of hoboes.

"In the matter of safety, I consider that furniture steel is the armour of better business. When I left Blank and Blank's and considered equipment for this plant, I decided what was necessary for safety, system and sanitation, and here it is. A fire is generally considered to be a remote proposition, but it is wonderful how little precautions sometimes prevent serious accidents. Had the waste paper basket, and the desk and cabinet near which it stood at Blanks', all been of steel, there would have been no fire. On the other hand, you may argue that it sometimes requires fire to make some people aware of the chances they are taking."

The above story is not fiction. There is some such circumstance as that described at the back of most instances where the triple "S" in business is being linked with steel, even in places where one would least expect to find it. System would hardly seem to be complete when it did not take the other two into consideration, and so the three may be said to interlock or be dependent upon each other.

Fire, of course, is not the only danger. The chance of valuable tools, parts, or quantities of valuable materials being mislaid or stolen, or turning up missing

Steel bins for miscellaneous parts and small castings.

Systematic Layout of Steel Store Bins

is always present and probably there are cases where they are quite as difficult to guard against.

For the Large Plant

During the war, the impression of system and safety was strongly emphasized, and steel equipment stood up to all requirements. Today it will be found that many large machine shops

Small steel office safe

and manufacturing plants have adopted, or are gradually introducing, this material throughout their entire plants and offices. One instance that is quite mentionable here is the plant of John Bertram & Sons Co., Dundas, manufacturers of machine tools. They have a system of steel factory shelving, used for storing small tools, also bolts, screws, nuts and small machine parts. The wood shelving formerly used had its disadvantages. Tools thus stored represented a large amount of money, and it was desirable to reduce fire chances to a minimum. Then, wood did not have the carrying or wearing capacity. The steel shelving is partitioned in such a way, and is so adjustable, that the stalls can be arranged in a unit system that is particularly useful. Bin fronts are used

Neat arrangement of steel clothes lockers

in some cases to better accommodate quantities. The draughting room is also steel-equipped throughout.

Adapted to Many Uses

What has been done in the plant of this large Dundas industry is also apparent in other plants according to requirements. For example, a large phonograph concern has installed a series of steel bins or cabinets for the storage of record discs. Golf clubs are installing wardrobe locker systems of steel, enamelled to suit club house decorations. Storage warehouses have steel stairways, balconies, lockers, cages, doors, window sash, etc. Steel and more ornamented metals are being used by banks and large business offices. Large vaults are of course fitted with steel shelving, and movable racks; steel is specified in much modern sanitary equipment, and lavatory compartments of metal are being frequently installed.

The very fine finish that is possible in furniture steel makes it adaptable to private and public offices for safes, cabinets, filing racks, lockers, desks, tables, guards, railways and partitions, while for hospital equipment, it seems to be the last word for purposes of utility and sanitation. It is, moreover, adaptable in all cases, to ornamental effect.

The advertising man is finding steel exceedingly useful, not only in plain name signs, but also in working out striking effects in electrical publicity. There is no quarrel with wood. It will always be preferred for certain purposes but the age of steel is developing a headway that seems to work in admirably with the requirements of the triple "S"—Safety, System and Sanitation.

Introducing

W. A. BOWIE

"Where is Bill?" If you hear this remark inside, or within shouting distance of the Ford-Smith Machine Co. plant at Hamilton, Ontario, you can almost feel sure it is the above pictured gentleman they are asking for. His real name is William, but if somebody were to use this dignified form of speech, ten chances to one, Bill would think they were talking to somebody else.

He is one of the happy-go-lucky type, has travelled extensively and learned much en route. Since his birth in 1882 at Glasgow, Scotland, he has been a searcher after knowledge, and although only able to secure a public school training, he made the most of his opportunities.

After finishing school, he went to John Lang and Sons', machine tool builders in Glasgow, and served a 5 years' apprenticeship. Six months after his time was out, he came to Canada and started work as a fitter in John Bertram & Sons, Dundas. He stayed there about 4 years, when the wanderlust became evident once more, so off he went to the Brandon Machine Works, Brandon, Manitoba. He tackled bench work for a year and also worked for the Manitoba Pump Works, then back he came to the London Machine Too Co., at Hamilton, as general fitter.

Later, he took charge of the heavy work at this plant, and also acted as outside man, going on the road and setting up various installations. Then the Canada Machinery Co., Galt, purchased the London Machine Tool factory, but Bill stayed on under the new management.

After they broke up their Hamilton plant, he moved to Galt, and altogether was about 12 years with both companies.

In his time he has built many special machines including brake lathes for the International Nickel Co. and was up at North Bay, Winnipeg, and other points, installing air hoists, brake lathes, and varied equipment including an 8 ft. long boring mill at Sherbrooke, Que. He has even been on the road selling machines, so knows both ends of the business.

He went to Ford-Smith's in 1917, and started to work on the bench. During the war, Mr. Ford-Smith had to open two additional plants, and Bill took charge of one of the new sections. After the sudden rush had disappeared, he came back to the newly-built plant as assistant foreman and later was made superintendent, which position he still holds.

The best quality about Bill is that he knows a lot, but does not attempt to impress you with this fact. He is a good mixer, knows his men personally and after working hours you'll usually find him driving his automobile along the Toronto-Hamilton highway, sitting well back in the seat with a smile on his face as much as to say, "Worry—what does the word mean?" and yet, in spite of the smile more than likely he is planning some scheme to overcome a problem at the factory.

BOOKLETS

The Canadian Ingersoll-Rand Co. has just issued a revised treatise, in the form of a booklet, on the Lubrication of Air Compressors. The matter is a reprint of an article prepared by H. V. Conrad, M.E., former secretary of the Compressed Air Society of New York.

Correct Lighting Dependent on Proper Diffusion

Getting the Most from Natural Daylight—Modern Plants Constructed With That Object in View—Coating Walls With Light-Reflecting Colors—Better Lighting Systems.

WE HEAR a great deal these days about more light, about lumens, foot candles, light intensities, light utilization, etc., but there is one thing about which we do not hear so much and of which we should hear more, and that is proper light diffusion. For example, a battery of closely-spaced automobile headlights suspended from the ceiling of a building would certainly emit enough light. There would be sufficient lumens, foot candles, light intensity, etc. (more than enough, in fact). But no work could be done under such a torrent of concentrated light rays, the light not being properly distributed or diffused. Such light would be too strong for eyes directly in its path, and it would throw such decided shadows that everything else would be dark by contrast.

Correct lighting, then, is as much a matter of correct light diffusion as candle-power. A room in which foot candle readings would give a value of 6-foot candle in one section, and ½ foot-candle in another section not 20 feet away, could hardly be said to be well lighted. Because, while 6 foot-candles is probably almost sufficient light for the most particular work, ½ foot-candle is hardly enough for an auditorium or for the aisles and passageways in an ordinary building.

Artificial Light vs Daylight

It is true that this difficulty can, to a very large extent, be remedied by the proper placing and selection of the right kind of electric light units for this purpose. But the point that must always be borne in mind is that artificial light first of all represents an expense in installation and maintenance, and second, that however desirable, it is never as good as daylight. This fact is so well recognized that in some countries, as for example, Holland, legislation forbids the employment of women and children in workrooms from which daylight is excluded. There is a reason why.

Extract from an article in Building Maintenance issued by the Truscon Laboratories.

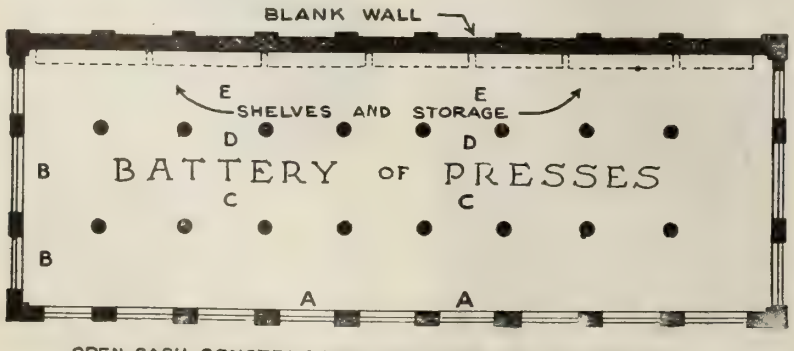
Daylight, as Sir Isaac Newton pointed out, is not a basic or elementary light color, but a combination of colors so mixed (let us say) as to give an impression to the eye of what is commonly referred to as "white light." A ray of sunshine, on being passed through a glass prism, is broken up into many rays representing all the colors of the rainbow. These various colors of their individual specific intensities and volumes make up what is known as daylight. No form of artificial light so far devised, on being broken down or analyzed by the spectrum, shows this same record of component parts as natural daylight.

Superiority of Daylight

It, therefore, follows that artificial light cannot be the equivalent of daylight, since in the history of our race the sustained use of artificial light and the intensive application of the eyes under artificial lighting is but a comparatively recent innovation—the development of the visual organ having evolved under the stimulus of natural daylight.

We must admit, however, that wonderful strides have been made in the perfection of artificial illumination and its proper use, and we do not wish to detract from such genuine accomplishment. But the fact still remains, and we must recognize it, that artificial light at its present stage, is but a poor approximation of daylight, a makeshift. It is but an attempt to imitate the standard represented by daylight.

It is evident, therefore, that the more favorably we arrange the construction of our industrial plants, office buildings and homes, so as to enable us to take the fullest possible advantage of daylight, the better the quality of light we will obtain. Hence the popularity in the last decade of what is known as "daylight construction," especially among industrial plants, as exemplified in steel sash walls, sawtooth roof construction, etc.



All of which holds a strong brief in favor of the utilization of natural light—sunlight. It will immediately be pointed out that sunlight in some of our industrial centres at certain periods of the year is doled out in a very parsimonious fashion. It then becomes a matter of utilizing this artificial illumination so as to get the maximum benefit out of it. Similarly, we are equally concerned with getting the maximum use out of whatever daylight with which we may happen to be favored. Luckily, in this effort, we are assisted by certain characteristics of light, namely, its faculty of absorption and reflection from surfaces.

Absorption and Reflection

All opaque surfaces absorb light. Some opaque surfaces absorb more light than others; what they don't absorb they reflect. Objects are seen by the light they reflect. Colors are distinguishable by the light they reflect. A piece of red fabric has the ability to reflect chiefly the red rays of the visible spectrum. Consequently, when white light falls upon the red fabric, only the red rays are reflected while the remaining visible rays are absorbed. By this process of absorption and reflection, the colors of pigments and most of the colors in nature are produced. But also by the same process much light is lost. What is absorbed is lost—in illuminating value, that is evident.

Absorbed Light is Wasted Light

This point is of real significance in the lighting of the interiors of buildings, because no matter how powerful and adequate the source of light we use may be (artificial or natural) that source of light is robbed of its effectiveness if the character of its surroundings is such as to absorb too much light. It is like a locomotive with a burst steam pipe. The source and quantity of

OPEN SASH CONSTRUCTION THIS SIDE AND END WALLS

Fig. 1.—General ground plan of a printing plant.

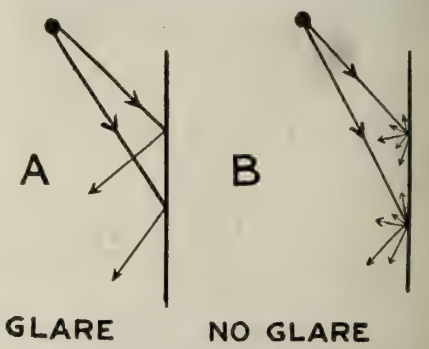


Fig. 4.—"A" represents direct reflection from a polished surface, such as a mirror or enamel surface. B represents diffused reflection, as from a flat, unpolished surface. The quantity of light reflected from both these surfaces may be the same, but in the case of A it is more intense and results in a glare, whereas in B there is no glare, but a soft, eye-restful light.

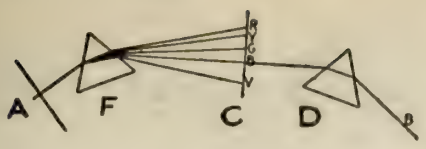

Fig. 2.—Newton's Experiment. A ray of daylight from the source (A), on passing through the prism (F) is broken down into its component colors; red, yellow, green, blue, violet, at (C). That each of these colors is not capable of further decomposition is proven by passing one—blue, let us say—through the prism (D). It is still refracted as blue.

steam is adequate, no doubt, but the steam cannot be put to effective work.

Similarly, a room painted a deep red or a dark gray will not seem as bright as another room painted a lighter color, lighting conditions being equal. Photometric readings in both these rooms will disclose a decided difference in the light distribution and intensity, especially in those sections away from the windows. Why? Because the walls of a dark red color absorb from 85 to 90 per cent of the light entering the room, while the walls and ceilings of the proper color will absorb only 15 to 25 per cent.

Here then we put our fingers on one of the greatest sources of waste ever discovered, the waste of light. Truly may it be said: "What does it profit a man to instal the best artificial lighting system that engineers can devise, if four-fifths of the light so obtained is to be consumed by murky walls?" Why employ daylight sash construction if the interior of each floor is to be overshadowed with dull, gloomy light-absorbing ceilings and columns?

An Example

An example of this comes very forcibly to mind in the case of a large printing plant where engineers were called in for consultation on their lighting problem. A ground plan of one of the floors of this printing plant is shown in Fig. 1. Observe that this floor, with a width of only 50 feet, had daylight sash construction on three sides. Surely the owners made sufficient provision for light to satisfy the most exacting requirements. Yet, they were not satisfied. Nor would any one who entered the building have been satisfied.

On a bright, clear day, at 2 p.m., the foot-candle reading on the floor, at street level, three feet from the window, at the points marked A, was only 3 (sufficient light for ordinary operations, but poor considering nearness of location to window). At the points marked B (the south or sunny side of the building) the reading was higher—5½ f.c. —but in the interior of the plant, at points marked C, D, and E, the readings ranged from ½ to 2. On this same floor was a battery of large, flat-bed presses. The feeders engaged at work on these presses stand on platforms, which bring their shoulders within four feet of the ceiling. Foot-candle readings here in the middle of the afternoon of a bright day in October gave values of from ½ to 1, necessitating the continued use of shaded electric light.

Four weeks later, after the recommendations of the light engineers had been put into effect, the foot-candle readings on no part of this floor were less than 4½ (without artificial light) with 6 to 8 as a general average except near the windows, where the reading ran up to ten. This was still further improved by removing rust and encrusted dirt from the ribbed glass windows.

A curious fact, however, is that white paint tinted with ever so small a quantity of black, drops down considerably in its lighting efficiency—as much as 15 to 20 per cent. This means that the grays are, in comparison with white, relatively poor light-reflecting colors. This phenomena explains why plain, gray

Fig. 3.—Recomposition of white light. That the colors resulting from Newton's experiment, illustrated in Figure 2, are not produced by refraction, but represent the actual mingling of these colors to form white light, is proven by placing a second prism, identical with the first, in the position (D) (above). (S) in this case is the beam of light which is decomposed into the spectral colors by the first prism and recombined into a beam of white light at E.

concrete walls and ceilings darken a room—why soiled and grimy walls of any kind are an enemy to lighting efficiency as well as to health and sanitation. Their light-reflecting value is often as low as 25 to 30 per cent. They absorb light—they waste it—just as surely as a burst steampipe on a locomotive wastes power.

Another curious fact brought out by these experiments is that a dull or flat white surface has a higher light-reflecting co-efficient than a gloss white. Heretofore, it has always been taken for granted that the gloss, on account of its brilliant finish, must have a higher reflecting value than a dead flat white. However, this is a feature of interior illumination that we will take up in greater detail a little later.

Lighting Efficiency

No lighting system can be efficient if it has to put up with drab and murky surroundings. True enough, the system may provide sufficient light. But this is no criterion. The unalterable physical fact still remains that dull walls, ceilings and columns absorb light. And the lighting system has to be made powerful enough to overcome this enormous wastage, to provide sufficient illumination, notwithstanding.

If the source of wastage could be materially diminished, it would very soon be seen that the lighting system under the new conditions is too powerful. In other words, a proper consideration of the illuminating problem from the standpoint of light-reflection from its surroundings, saves money on illumination units and illumination maintenance.

Spreads the Sunshine Inside

It is because of this generally recognized fact that the method of applying a white coating to interior walls and ceilings in manufacturing plants, warehouses, auditoriums, etc., has become so much the vogue. Various materials can be used for this purpose—whitewash, kalsomine, oil paints—anything white, one might say, but this is not true; as many other factors besides whiteness must be taken into consideration.

Disadvantages of Cold Water Paints

A coating must be selected with a due regard for its fitness to its surroundings. Whitewash, for instance, could never be used in a pure food plant—the whitewash would be continually flaking off and dropping into the manufactured product. Nor could kalsomine or a

Fig. 5.—A difference as of between day and night. The section of the photograph at the right shows the appearance of the interior of a new tire plant. The walls were not black—they were simply normal concrete grey color. But the camera shows how much light was lost in this plant by the dark appearance of the photograph. The section of the illustration at the left has been retouched to give an idea of what the same interior would look like if walls, ceilings and supports had been coated with a white, light-reflecting materiel.

cold water paint be used in such a place. Coldwater paint is an organic product composed principally of casein, glue, dextrin and such materials which offer nutriment to the growth of fungi and molds, and which naturally contribute to an unsanitary condition.

Both these materials, on account of the porous nature of their film, absorb a considerable quantity of dust and dirt, and darken quickly. They are not washable. In a word, they are hardly worth the cost of application. As a matter of fact, they are a decided detriment, because, should the owner afterwards decide to use a good oil paint, he would be forced to go to the expense of removing all this old coating from the surface.

White Oil Paint the Ideal Coating

In conformity with the latest developments in the art of interior decoration, coatings should be of a character to offer a hard, non-absorbent surface, which does not readily collect dust, which is non-poisonous, which offers no possible nutriment to bacteria, and which, if desired, can be washed freely and kept clean. And—the coating should be light-reflecting—white being invariably the most efficient shade.

White oil paints, therefore, are most suitable for this purpose, especially oil paints which are free from white lead and poisonous ingredients. Such oil paints are generally known as mill whites. They are obtainable as flat coatings (usually used as the undercoating), enamel or gloss coatings, and coatings which produce a finish between the flat and gloss, known as "eggshell."

Requirements of a White Oil Paint

The development of mill white paints in the past ten years has been extraordinary. Consider the requirements that such a paint must fulfill. It must have all the qualities of a high-grade, durable paint, of maximum light-reflecting value, and yet be procurable at a price to justify its being used over enormous areas of interior wall surface. But that is not all. White paints have a peculiar tendency of turning yellow, especially when not exposed to much daylight. Naturally, the darkening of such a coating would in time considerably diminish its light-reflecting value.

What Constitutes a Good Mill White?

In a market flooded with materials intended for increasing the lighting efficiency of plant and office interiors, it is probably confusing to one who is not familiar with paint values, to determine just which material is best suited to one's purpose. Under such circumstances, we believe it would clarify the situation at this time to discuss the requirements that an efficient interior white should measure up to, and how the value of these various requirements can be measured so as to form a basis for comparison.

The basis that we recommend for determining the merits of various mill whites is a competitive test conducted by the building owner, under his own supervision, so he will be in a position to judge at first hand the relative merits of the material offered for his attention. Such a test naturally, in order to be fair, and to form a correct basis for comparison, presupposes that all materials should be applied by the same painter over similar surfaces, and subjected to the same uniform conditions of test throughout.

Suggestions for Test

The suggestions as we present them are prompted by our experience with interior white paints, as a result of which we are able to judge a paint accurately on its various chief merits. These chief merits on which we should judge an interior light-reflecting coating are five in number, as follows:

No. 1—Whiteness or light-reflecting value.

No. 2—Permanence of whiteness.

No. 3—Covering capacity per gallon.

No. 4—Opaqueness, or masking value.

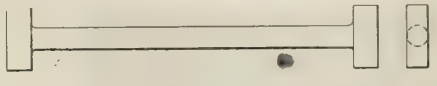
No. 5—Ease of brushing and labor cost.

(To be continued.)

Replacing Hand-Made Parts By Suitable Forge Machines

By WM. JAYNES

AFTER many years of experience in connection with forge work of a varied character, the writer is considerably surprised to learn that ship builders do not make more extended use of bolt-heading and rivet-making machines. In the yard where I am now employed, and from which a number of steel vessels have been launched, there is no sign of a bulldozer or rivet machine. Take as an example, the writer has operated machines for the making of rivets at a cost of 30c per 1,000, and where over 500,000 rivets are used in the construction of one vessel, it seems that it would pay to install equipment for this work.

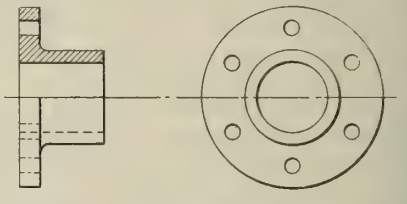


Take another case, that of the making of ladders and gratings—would a man and helper shear 250 rings and forge both ends in 9 hours on the anvil? The writer has made over 5,000 bolts a day on a bolt machine. Would it not be possible to have a collar pressed on each end similar to the sketch below?

With a production of from 2,000 to 3,000 per day. Or the ends could be swaged, like the piece here shown, in a bolt machine. Figure the saving on four ships, for all the ladders and gratings needed.

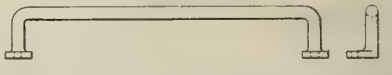
Take shackle making in a bolt machine and compare it with anvil work. Take staunchions like this:

How long does it take to split these ends, throw back and finish up? The anvil method does not make a satisfactory job, and the work could easily be accomplished in one heat on a suitable forging machine.



Take ladder handles, with a ball on one end and an eye on the other—how easy these could be made on a bolt machine.

For staunchions on gangways a ball could be pressed, flattened, punched and rounded in one heat.



Compare this to splitting the stock, opening the eye and other detail operations a blacksmith would require to do in performing this work.

Another job that might appear to be out of the usual range of the forging machine is the pipe flanges used on ships. The making of these under the steam hammer is a slow job. The flanges could be successfully made in one heat on a suitable machine. The

sketch herewith is of a flange with a 3 in. hole, the collar being upset from 3in. stock and punched clean off from the bar, and the latter is ready for the next heat.

Take ladder irons with an eye on each end, such as here shown.

What a lot of drawing and swaging under the hammer—these can be upset, punched and bent in one heat on a forging machine.

Another common job is the making of stay rods, used to support staunchions to deck; a sketch of the stay being produced here.

Machine work on this job would reduce production cost by about 75 per cent. Many other cases of work that are now done by hand could be economically produced in suitable forging equipment.

News From the Welding Field

Some Problems of the Job Welding Shop

Work Almost Entirely Repairs—Preparation, Welding and Finishing—Experience the Chief Guide—Welder Must Have Good Memory and Keen Observation—Customer's Needs Must Be Considered.

By S. W. MILLER

BY A JOB SHOP is meant one which takes in any kind of work which is brought to it. The work may be large or small, easy or difficult, and there may be much of one kind or there may be no two jobs alike. The job welding shop comes under this specification but has an additional difference. The work is almost entirely repair work. In repair work of any nature the objects are to have the repaired part strong enough to stand the service required of it, and to do it at a price as low as possible, consistent with good workmanship and a fair profit. There are many difficulties in accomplishing this result in a job welding shop.

In considering these difficulties, we will confine our attention to repair work because in production work the difficulties can be overcome in the course of a short time, and after this has been done, the rest of the work is comparatively easy. The difficulties in a job welding shop may be classified as follows:

First, the work itself. Second, the varied natures of metals that are of the same general type. Third, financial problems. Fourth, guarantees on the work.

Work

The first head may be subdivided into the following:

"A"—Preparation.

"B"—Welding.

"C"—Finishing.

The preparation of the work involves the making of the V, the method of lining up the work, and the arranging for and taking care of the expansion and contraction.

The welding covers the decision as to whether gas or electric welding be employed, and upon this decision somewhat depends the preparation. The method of pre-heating really should be considered in connection with the welding, although it is important enough in some cases to be considered separately.

The method of finishing the work, if finishing be necessary, as do all the other operations, depends on the facilities on hand. It is difficult to lay down general rules for any of these matters and it is probably best to consider what has been done in individual cases.

Varied Nature of Metals of Same General Type

Under the second heading, it should be remembered that in a production job the material used can be specified so that uniformity can be obtained, which enables the welder to use the same methods and practices at all times. In repair work, however, not only are the materials, for instance, cast iron, not uniform, but in many cases it is impossible to determine before the welding is started how the material is going to act during the welding process, and sometimes changes in methods have to be made in order to overcome difficulties of this nature that could not be anticipated.

The only thing that will guide a welder under such adverse conditions is experience, and to use this experience the welder's memory must be good and his observation keen.

The job shop is called on to handle all metals and it is seldom that one finds a welder who is able to do all of them well and still rarer to find one who is capable of doing all-round welding with both gas torch and electric arc.

It is sometimes difficult to distinguish between cast iron, malleable iron and cast steel. It is frequently impossible to distinguish between the various brass and bronze alloys and many failures have occurred because of these troubles. Similar difficulties exist with other metals, so that the job shop, to be successful, must have a wider knowledge of metals and their characteristics than any other kind of a shop.

Financial Problems

Third, the majority of job shops do not have any real knowledge of their costs, and it is frequently the case that where there are a number of competitors in the same city, prices will be cut and recut until the work is being done at an actual loss by everybody. Such a condition is bad for the welding industry, but it will not be overcome until such shops see the importance of knowing what the work costs them. To do this is not so difficult, but does require a proper system of bookkeeping and a simple accounting method. Any good accountant will, at small expense, instal a suitable system, but he must bear in mind the character of the average job shop, which is not competent to understand or to use complicated methods, and which do not have time to spend in using elaborate blanks, slips, tickets, etc.

The nature of the system installed depends upon the work being done, and it is impossible to give any specific data. It will be enough to say that all the time put on the work must be accounted for and that an approximate idea of the gases or current consumed must be known. Allowance must be made in the gas cost for gas that is not used from the tanks, especially in the case of acetylene, where quite a little of it cannot be used especially in cold weather.

On the other hand, too much time must not be occupied in collecting accounting data, because if this be done it may cost more to get the information than is saved by getting it.

The items that are most frequently overlooked are those that are usually called overhead expenses, such as insurance, taxes, repairs of apparatus and advertising. I do not mean that these expenses are not paid, but that they are not included in the charges made for the work in an intelligent way. Of course if the real cost of the work being done is not known, it is impossible to say what the charges should be, and charges must include a profit over all expenses, or else the business will fail.

In connection with the financial end of the business, the treatment of the customer is of vital importance. A satisfied customer is the biggest asset of the business. Of course a customer cannot be satisfied unless the work is done properly, and at a reasonable price. The most essential thing, however, is to do the work properly, even if in some cases it has to be done at a loss, and as a matter of policy, I believe it is wrong to do cheap work; that is, work that is deliberately so done, even with the understanding that first-class work is not needed. Of course, if the best work is not really necessary, it is wrong to spend more money on it, but it is a frequent occurrence to have customers ask

Material prepared by the author for presentation at a recent meeting of the American Welding Society.

for a cheap job in order, for instance, that they may dispose of an automobile, their idea being as soon as it is off their hands they are not responsible any further. But a moment's thought should convince us that such a policy is unfavorable to the welding shop, for if the part fails, no excuse on the part of the welder will remove from the mind of the owner of the car the idea that he has been injured and that welding is of no value. It is far better policy to refuse to do work of this character. Further, it is much easier to explain to the customer that good work has been done and to collect the money for it, than it is to explain an unsatisfactory job.

Inasmuch as many customers are entirely unfamiliar with welding, it is frequently necessary to go into detail as to the reasons for doing certain things. The customers frequently cannot understand why an intricate casting has to be pre-heated and slowly cooled, but if the matter is explained to him in a careful and thorough manner, he is usually willing to accept the explanation. If he is not willing and can not be made to see that a certain procedure is necessary, it is far better to let the work go than to do it in a way which the welder knows will be unsatisfactory. On the other hand, if the welder is so unfortunate as to do a piece of work badly, the best policy is to honestly admit and explain why. There are so many jobs that come to the welding shop that have never been done before that it is no wonder that failures sometimes occur, and honesty in this, as in all other cases, is the best policy. I speak of these things in some detail because they are many times overlooked or not understood or appreciated.

Guarantees

A welding shop is frequently asked if it guarantees its work, and such shops frequently advertise that they guarantee all jobs. A general statement to the effect that all work is guaranteed in reality means nothing and there should be some specific form of guarantee covering all usual cases.

It is also well known that, in all probability, a general statement as to any guarantee is not legally effective unless it is specifically called to the attention of the customer before the work is undertaken, and if it is not intended to guarantee the work, the customer should be advised of this at the time the work is taken in, and in important cases the further precaution of notifying him in writing should be taken.

Again, a guarantee is of no greater value than the ability and willingness of the welding shop to fulfill it. It may be that the financial strength of the welding shop is not sufficient to properly guarantee some important work. In such a case the safe course to pursue is to have the work done by some larger shop in order to avoid financial loss.

Whatever is done in the way of guarantees should be done as a matter of principle, and the policy should be followed strictly and altered only as experience indicates that changes may be safely made.

Precautions

As in all other work, welding has its tragical and humorous sides. The tragical may be well represented by the accidents that have occurred either through lack of knowledge or pure carelessness, as when tanks that have contained oil, gasoline or other explosives, have been worked on with a cutting or welding torch. It is equally dangerous to work on them with the electric arc. Explosions have occurred even after a tank has been washed out with water, or steamed out, so that the only safe way is to keep the tank as full of water as possible while the work is being done. It should first be filled entirely, care being taken to see that all pockets are filled. The water can then be let out just enough so that the welding can be done.

It is a good rule to keep visitors out of the welding shop unless they are accompanied by someone who can take care of them. It is also a good rule to keep beyond possible range of the torch flame. Some welders have a habit, which is a bad one, of turning the torch flame toward their shoulder in order to look at the work, and I know of one case where a man who was standing back of the welder had the torch flame turned in his face.

The dangers of looking at the electric arc are well known to you, and in all cases precautions should be taken so that even side flashes from the arc may not get to anyone's eyes. It may sound incredible, but there is one instance on record where a welder endeavored to stop a leak on an acetylene generator by welding with, of course, fatal results. In my own experience I had a welder, whom I employed temporarily, build a small charcoal fire on top of a Prest-o-Lite tank during cold weather, in order, he said, to thaw out the acetylene regulator. Fortunately, in this case the fusible plugs operated, and while the flame shot twenty feet in the air, no damage was done.

There are many humorous questions asked by customers; that is, they are humorous to us. One of these questions is quite frequent, that is, whether cast iron can be welded. Courtesy and tact demand that we should not smile under such conditions, but that a careful explanation of the principles of fusion-welding be given, so that the customer may understand that all metals may be joined together by these processes. Then his idea of welding will be broadened and his confidence in it increased. It is even sometimes necessary to demonstrate to the customer that metals can actually be melted together. As a matter of fact, we can all be asked questions in connection with welding which we are unable to answer, and people that live in glass houses should be careful about throwing stones.

£10,000 FOR RESEARCH

The name of Parsons is known all the world over in connection with the invention of the steam turbine which has made possible the cheap production of electricity in large quantities and the development of high speeds by large ships. In addition to inventing the turbine Sir Charles Parsons has rendered great service to the progress of science and the latest sign of his interest in the field is the gift of ten thousand pounds to the British Association for the Advancement of Science. Since it was founded in 1831, the Association has made grants of over eighty thousand pounds towards scientific research. Sir Charles' latest gift will enable the Association to maintain its important work of scientific investigation. In connection with the speed of ships it is interesting to note that the fastest ship afloat is a British vessel, the "Mauretania," and during a recent voyage from the United States to Great Britain she maintained an average speed of 25.14 knots, and at one stage she attained 27.5 knots. This was the fastest trans-atlantic cruise made since the war, and it is faster than the same vessel had ever attained.

BOOK REVIEW

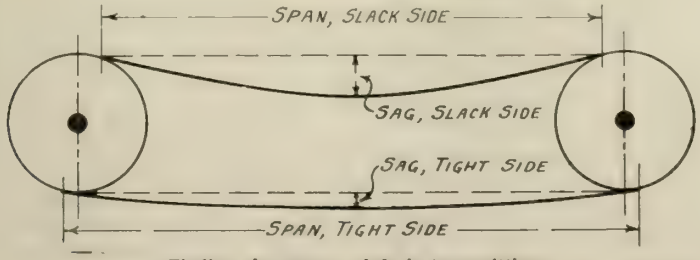
The Penton Publishing Co. of Cleveland, Ohio, have just issued a Foundrymen's Handbook, in which has been compiled the "data sheets" that have been appearing in Foundry for many years. This book is a complete and up-to-date reference on all foundry problems. It comprises all necessary knowledge from the estimating of the price to the cleaning of the finished casting. Section II, contains the formulas for computing the weights of castings of all shapes and sizes in any kind of metal; Section IV, gives the compositions and physical properties of every known non-ferrous mixture, data on fluxes, deoxidizers, pickling solutions, melting points, strengths of metals and alloys with the effect of different brass additions, and suggests to the brass foundryman the proper choice of metal for given requirements. Section V, gives the standard specifications for gray iron castings, cast iron pipe, cylinders, special castings, scrap metals, case hardening and annealing; Section VI, gives miscellaneous tables of every-day use in the foundry, such as gross and net ton equivalents, tables for conversion of weights and measures from U. S. to metric system and vice versa, etc., etc. The book is 6 x 9 in. and contains 309 pages. Price $5.00 postpaid.

The White Star-Dominion Line have had the freighter "Irishman," which was formerly on the New York run, diverted to Montreal. She arrived in that port June 6th and loaded one thousand head of cattle for Avonmouth. This is the largest cattle cargo ever shipped from Montreal. The steamer is a twin screw boat of 21,000 tons, being the largest freighter that ever docked at Montreal.

Practical Ideas From Practical Men

HOW MUCH POWER IS THAT BELT TRANSMITTING

(A method that gives the answer without the use of complicated instruments.)



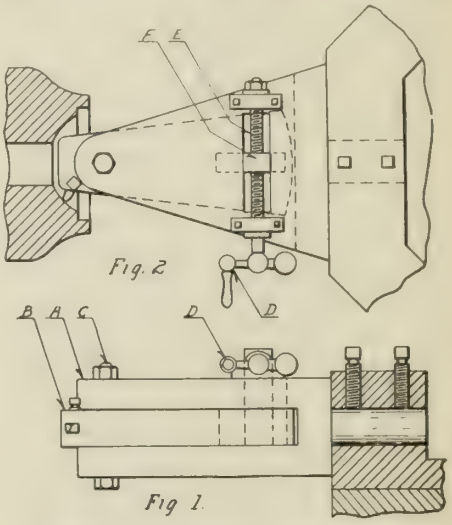
By W. F. Schaphorst

When a horizontal belt is in operation, and most important drive belts are horizontal or nearly so, it is a well known fact that no matter how great the load that is being transmitted there is a sag in the "tight" side of the belt as well as in the slack side. It is impossible to make the pull so great that the tight side will be perfectly horizontal, or a perfect straight line. There will always be a sag. The greater the load, the less the sag on the tight side and the more the sag on the slack side.

In view of the fact that this sag on both sides varies with the load being transmitted and in view of the further fact that the tension in a belt can be accurately computed when the sag and span are known, it becomes possible to compute the power being transmitted by any horizontal belt. To assist in these computations the writer has prepared a table which is reproduced herewith. It is a simple matter to measure the sag and the span with an ordinary yardstick. Four other measurements are necessary—the width and thickness of the belt; the outside diameter of one of the pulleys; and the revolutions per minute of that same pulley. These measurements may all be taken with the same yard stick and with an ordinary watch.

To determine the horsepower being transmitted by a given leather belt of any width and thickness, measure the span of the slack side as indicated on the sketch. This span is NOT the distance from center to center of the shaft but is the distance between the points where the belt leaves one pulley and touches the other. Then measure the sag. The sag is the greatest vertical distance between the belt and a straight line connecting the contact points as shown on the sketch. Next, measure the span and sag of the tight side again, observing the points of "making and breaking contact" as explained above. It makes no difference whether the belt is a "bottom pull" or "top pull" belt, this method will give the horse power transmitted in either case. Then, referring to the table, find the tension corresponding to the span and sag of the slack side, which we will call A. Then find the tension corresponding to the span and sag of the tight side, which we will call B. Subtract A from B. Then multiply by the width of the belt in inches. Then multiply by the thickness of the belt in inches. Then multiply by the outside diameter of one of the pulleys in inches. Then multiply by the revolutions per minute made by that same pulley. Then multiply by .000007933. The answer is the horse power being transmitted by the belt at the same time of measurement.

In case the sag is less than one inch, which may often be the case where pulleys are close together, this same table can be used by simply shifting the decimal point to the right. Thus if the span is 10 ft. and the sag is 0.6 in. instead of 6 in. the tension would be 105 lbs. instead of 10.5. If the span is 12 ft. and the sag 0.1 inch, the tension would be 907 pounds instead of 90.7. In case the actual span of the belt does not agree with the span given in the table it is a simple matter to "estimate" the tension from the table. For example if the span is 8 ft. 6 inches and the sag is 1 inch. The tension would be midway between 40.3 and 51. To find this midpoint add the two figures together and divide by two. The answer is 45.65. Another way is to subtract the two members (50—40.3) which gives a difference of 10.7 in. Then divide this by two (10.7÷2) and we get 5.35. Lastly, add this to the smaller number (40.3+5.35) and we get the same answer:—45.65 pounds per square inch.

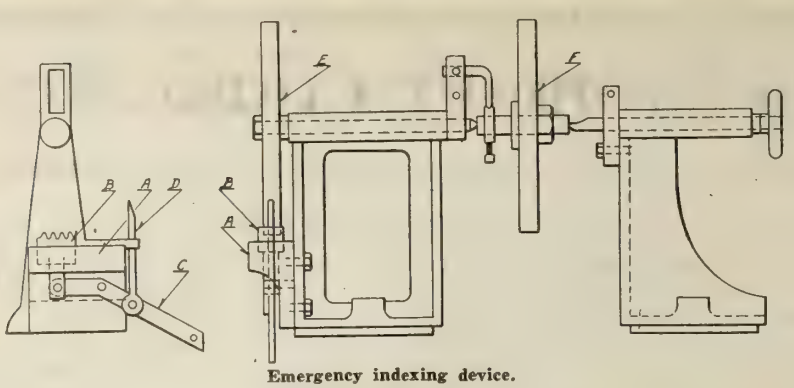


Finding the power a belt is transmitting

FIXTURE FOR MACHINING SPHERICAL SEAT

By H. Alton

In the modern paper machine there are a large number of steam joints in the piping system used for supplying steam to the drier and other rolls. There are many places where a spherical seat is required to take care of the above and other conditions met with in these pipe lines. A rather unusual little fixture was designed in the shops of the Dominion Engineering Works at Lachine, P.Q., to machine this type of seat. The castings are ordinarily machined on a turret lathe and to facilitate matters the above mentioned fixture was mounted on the turret. Fig. 1 shows an elevation of the fixture. As shown at the right the frame has been turned to fit the hole in the turret. The projecting part of the frame A is slotted to receive the block B that carries the tool. The block B is held in place by, and is permitted to rotate about, the pin C. The circular motion of the tool block B is controlled by the ball crank handle D. This handle is keyed to the feed screw E, and operates the brass nut F. This nut slides in a transverse slot in the frame and in a longitudinal slot in the block.



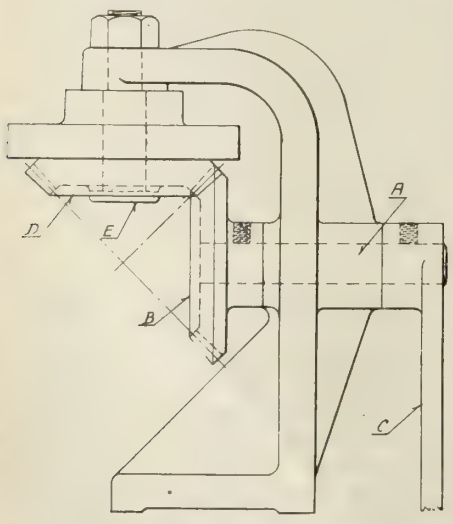
Fixture for machining spherical seat.

When using the tool the turret is advanced along the ways of the machine to bring the tool in contact with the work. The tool is fed by hand in either direction by operating the handle. The pitch of the screw is small and in feeding the ball handle is turned at about thirty to forty revolutions per minute. A very smooth and regular finish is obtained. The tool is ruggedly constructed and in spite of the apparent excessive overhang, the entire fixture is very rigid. As the cutting is rather light, a seat that is practically perfect, is obtained.

EMERGENCY INDEX DEVICE

By J. H. Houldsworth

The accompanying sketch illustrates a device we constructed for the cutting of these sample gears at a time when the writer was engaged in a small jobbing shop. The plant had no regular facilities for accurate indexing so the idea here shown was decided on and the results obtained were entirely satisfac-



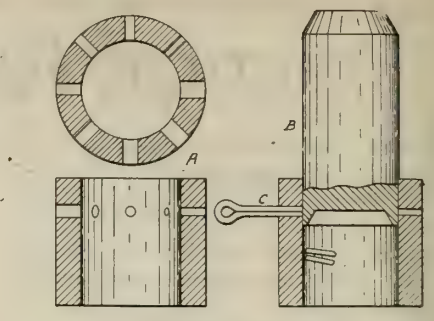
Emergency indexing device.

tory. Having a set of planer centres we removed the small casting that carried the worm and substituted the piece shown at A. This casting contained a small plunger B, the upper end of which had four teeth cut to fit those of the sample gear. The method of obtaining the pattern for the plunger was interesting. The sample gear was placed on a flat surface and blocked up, after which babbitt was poured in to get the shape of the teeth and top of the plunger. It was then cast and machined and made a good fit in the piece A. The lever C controlled the vertical movement of the plunger. This lever also operated the pusher pin D which was so adjusted as to engage in a tooth of the sample gear E on left hand end of fixture shaft. The release of the indexing teeth by the upward movement of the lever C allowed the gear to be revolved the distance of the pitch by the travel of the pin D, thus bringing the gear F to the next tooth position. This device was subsequently used for quite a number of gear cutting jobs but it necessitated a different indexing plunger with the desired tooth pitch. As a fixture for taking care of emergency work in the small shop the idea here shown was a distinct success.

TESTING FIXTURE FOR GEARS

By Robert Mawson

We use quite a number of bevel gears for transmitting the power to one of the types of machines manufactured at our plant and as these machines must operate very quietly and with the minimum amount of friction the testing fixture illustrated was designed and built to see that the gears were properly machined and the teeth accurately cut. The gears in the fixture occupy a similar relative position to that which they are on the assembled machine, so that we know if the gears run silently in the fixture they will also do so on the machine.



Testing Fixture for Gears

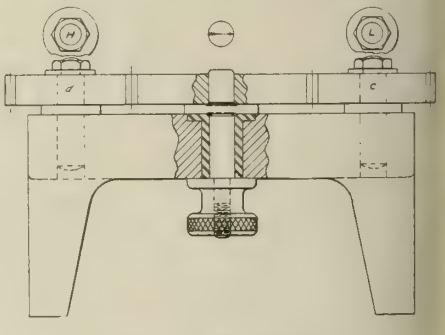
The fixture is made with a base provided with two holes that are used to hold bolts to fasten the devise to a stand or table thus holding it securely during the testing operation. The base casting has a vertical member provided with a long bearing accurately reamed to suit the shaft A. On the inner end of the shaft is fastened one of the gears to be tested marked B. On the outer end is attached a crank C and handle (not shown) the gear and crank being fastened by means of set screws. The frame extends upward to afford a horizontal member which is used to hold the other gear D to be tested, this gear being held in position by means of the stud and nut on the upper side of the fixture.

When the two gears are in the position as illustrated, the operator by revolving the crank C can easily ascertain if they are accurate or if a mistake has been made in their manufacture. If it is found that the gears are very defective it is sometimes necessary to reject them and return them to the machine shop for further machining. If the trouble be only slight, by placing an abrasive material on the teeth and revolving the gears the teeth can often be run in to operate smoothly. In fact, we have found that it is advisable on all gears to run them in, either by using emery or ground glass and oil or some grinding compound; in all cases care being taken to wash away the abrasive mixture with gasoline or kerosene after the desired smoothness has been obtained in the testing fixture.

It can be easily seen that this idea of testing fixture can be used on any pair of gears, bevel, spur, worm and worm wheel, etc., and the expense is well worth while as the shop is then positive that the driving members are what is desired as nothing detracts more from any machine than noisy gears, giving the customer the idea that the tool or machine has been poorly constructed.

Cutting split pins

CUTTING SPLIT PINS



By W. J. H.

The accompanying sketch shows a handy tool for cutting short pieces off split pins and small rods. The piece A is made of 2 in. cast steel bored to about 1¼in. and having a series of different size holes drilled through the wall. These could be drilled in irregular positions if desired. The punch B is turned to fit the bore of the ring and cupped at the cutting end as shown. A light blow of a hand hammer is sufficient to cut the average split pin.

GAUGE FOR TESTING SPUR GEARS

By N. F. P.

This gauge consists of two stationary spindles (c) and (d) with standard gears thereon. Between these two spindles is an eccentric spindle so made that its amount of eccentricity will determine whether the gear to be tested is too small or too large. The end of the spindle has an arrow stamped thereon which indicates as follows: if the gear being tested revolves when pointing to (L), it indicates that the gear is too small. If the gear does not revolve when the arrow points to (H) it indicates that the gear is too large.

Gauge for Testing Gears.

New Westminster, B. C.—Announcement has been made of the incorporation of the Westminster Paper Company, with headquarters here and capitalized at $250,000. It is the company's intention to erect a plant worth $100,000 on the North Arm of the Fraser River. It is understood that the new plant will specialize in the manufacture of tissue paper, a large market for which exists in the Orient and Canada.

New Things in Shop Equipment

ADJUSTABLE ANGLE CUTTER HOLDER

An adjustable cutter holder for use on turrets has recently been offered to the trade. It is intended to eliminate uncertainty in making fine adjustments. The cutter slide is operated by means of a graduated adjusting screw. The construction of this cutter provides accurate setting for finishing cuts. The head is made of hardened steel and is sufficiently strong to maintain the same size on each piece. The tool is being placed on the market by Warner & Swasey, Cleveland, Ohio.

QUICK OPERATION VISE HANDLE

To provide quick action of the movable block on machine vises a special handle has recently been developed. Owing to the long length of the ordinary handle it is very often difficult to quickly operate the screws on such vises, and it is often necessary to remove the handle owing to the inability to get a complete turn. This new handle is so designed that two square holes are made at right angles in the end. When tightening or releasing the vise the long lever is used, but when quick action is desired the lever is placed in the other hole so that the handle revolves in a smaller circle. They are made in a range of sizes to suit ordinary commercial work. They are manufactured by Bentley & Holmgrem, Bridgeport, Conn.

BENDING, FORMING AND SHEARING MACHINE

A machine for bending, forming and shearing metal has recently been developed and placed on the market. The machine is made in three sizes and is operated by hand, the smaller size being intended for bench use, and the two larger sizes for operating on the floor. All sizes of stock can be handled on the machine without extra dies, and the stock is so handled that no slip takes place. Holes are provided in the table for setting attachments to any desired position. By removing the forming and shearing plates all sorts of bending work of a heavy character can be taken care of. A 90 deg. angle can be accurately formed without the use of a gauge. The larger machine has an approximate weight of 840 lbs. They are manufactured by the Buffel Machine Co., El Paso, Texas.

DRILLING MACHINE VISE

A vise particularly designed for quickly securing all parts in drilling machines has recently been offered to the trade. All parts formerly requiring special jigs can now be handled economically in this vise. Lugs are provided on the base for securing to the drilling machine table. The handle of the tapping screw is swivelled to the end so that it can be operated conveniently in cramped position. The vise is made of cast iron with jaws 3in. wide, one and one-half inches deep, giving an opening four inches when full opened. The weight of the vise is 10 lbs., and it is manufactured by the J. L. Austin Mfg. Company, Milwaukee, Wis.

PORTABLE ELECTRIC GRINDER

A portable electric grinder of the squirrel-cage type has recently been placed on the market. A special treatment has been given to the asbestos insulation so as to bind the fibres into a tough, flexible mass, capable of withstanding a red heat indefinitely. The three-quarter horse power motor provided, quickly regains speed after slowing down due to heavy loads. The bearings are self-lubricating and of metal graphite type, the spindle operating at a normal speed of 3,600 r. p. m. A grounded wire is used to prevent the possibility of electric shocks to the operator. This protective wire adds little to the weight of these machines and can be attached to a water pipe or some permanent ground while the tool is in use. This portable grinder is manufactured by Forbes & Myers, Worcester, Mass.

HEAVY DUTY MOTOR GRINDER

There has recently been placed on the market a heavy duty motor grinder which is driven with a five h. p. alternating current motor. Ball bearings are provided and wheels 18 x 3 x 1½in. or 16 x 3 x 1½in. are used. The whole design shows that it has been built for heavy duty. The spindle is made of 45-point carbon steel. The end shields are of cast iron, turned with a recess and bolted directly to the motor frame. They are further secured in a position by supports clamped around the end shield hub, and then bolted to each side of the head casting. The end shield castings are turned and threaded into the ends of the shields. The flanges are turned all over and are recessed on the inside. Wheel guards are furnished, either plain or of the exhaust type, and are adjustable. Removable covers enclose the sides of the wheels, flanges, nuts, etc., for safety protection. The work supports are so mounted that their positions are adjustable. The starting switch is of the safety type, mounted within the column on a separate panel. This panel is easily removed from the rear of the machine without disconnecting the switch. The switch protects both operator and machine against unexpected restarting or accidental starting of the motor. It cannot be held closed on an overload. The standard machine is furnished as follows: 5 h. p., 220 volts, 60 cycle, 2 or 3 phase, or 550 volts, 60 cycle, 3 phase. The weight is approximately 1,200 pounds. The machine is manufactured by the J. G. Blount Co., of Everett, Mass.

TRIPLE COMBINATION PUNCHING AND SHEARING MACHINE

Recently there has been placed on the market a combination punching and shearing machine which is very economical in floor space and can be adapted to different types of work without the necessity of changing tools. The operator's side of the machine is clear of encumbrances such as fly wheels and driving gears. The plate shear has long knives, and behind these knives is ample room to ensure that no binding of plates will occur. The punch is arranged so that webs and flanges can be punched. The height of the throat is designed to handle broad flanged shapes. A lowering device is provided for the punch so that the centre mark can be ascertained. The frame is of cast steel. The slides are also made of steel and are adjustable. The covers of the slides are attached to the body by pin bolts so that they cannot work loose. The bearings are large, are bronze bushed, and are provided with ring lubrication. The machine is manufactured in a range of sizes by Amplex Inc., of New York City, and is marketed under the name Oeking.

SMALL ELECTRIC HOIST

A speed-reducing geared electric hoist has recently been placed on the market. The gearing consists of three internal ring gears, three planatory pinions, and a high-speed pinion that is mounted on the motor shaft. The outer gears of the internal set are housed in the frame so that they do not rotate. The middle gear which is keyed to the chain sheave has one more tooth than the outer gears. Long faces are provided on the planatory pinions to give ample bearing for the three internal gears. A speed reduction of from 100 to 1 and 350 to 1 is obtainable. Owing to the large speed reduction a high speed motor can be provided. As the mechanism is not reversible, no breaking facilities are necessary. The speed reduction gearing can be operated from the motor end only and no loads can be applied at the sheave that will cause the gears to rotate and thus lower the load. Roller bearings are provided and the motor shaft is subjected to driving torque only. Machine cut gears are used throughout and these are heat-

treated steel, with the exception of those used in the smaller hoist, which are made of cast iron. Either rope or chain lifts can be provided. These hoists are manufactured by the Joslyn Mfg. & Supply Co., Chicago, Ill.

AUTOMATIC DRILLING MACHINE

An automatic duplex drilling machine intended for high speed drilling, reaming, polishing and similar operations, has recently been placed on the market. Two spindles are mounted on the face of the column, each being rotated in a square guide block. Power is transmitted from the drive pulley to the spindles by means of noiseless bearings. A 3in. pulley is provided for the guide of the spindle, while a five-step pulley is provided for the feed and the operation of the chucks. The counter shaft which is mounted at the rear end of this machine carries two pairs of pulleys, one for each chucking unit. The construction of the machine gives a uniform downward movement to the spindle. It also provides a quick return on the upward stroke. The work-holding fixtures are made with four pockets so that special jigs can be provided for other work. The heads work alternately and are locked in position while the drilling is being performed. Feed is provided for each head separately. The machine has a capacity for drills or reamers up to 5⅛in. in size. These machines are manufactured by H. Ebsil Barr, Erie, Pa.

ELECTRIC PENCIL ETCHING OUTFIT

There has recently been placed on the market an electric pencil etching outfit which consists of two major units, a magnetic table and the pencil itself. It has been designed for the following uses: etching or writing on hardened steel, demagnetizing steel, annealing and soldering. By use of the magnetic table, work that has been placed on a magnetic chuck, can easily be demagnetized. To accomplish this it is merely necessary to pass the piece across the table while the current is turned on. In a similar way tools or bars may be magnetized. A file or other tool may be magnetized and used for removing chips from holes or for holding screws or other small pieces in place. To magnetize a tool for this purpose it is merely necessary to lay the tool on the table, turn on the switch, then turn off the switch and remove the tool. The etching pencil is used for marking sizes, numbers, and any necessary inscriptions on hardened steel tools or pieces. The cord of the etching pencil is attached to the table. When the current is turned on, it is possible to mark the work, with no more pressure than is required for ordinary writing. When used as an annealing point the cord of the pencil is attached to a second connection on the side of the table. The point is then replaced by one made of carbon, and the work is placed on the table of the intrument. When the current is turned on and the point of carbon held on the work, the point of contact begins to glow with heat. In this way a small spot can be heated without affecting the rest of the work. The carbon point may be employed in the same manner for soldering, being held in contact with the work to heat it and cause the solder to flow. The outfit is operated from an ordinary lighting circuit of 110-volt, 60 cycle, alternating current. The manufacturers are the Luma Electric Equipment Co., of Toledo, Ohio.

ARMATURE TESTING DEVICE

An armature testing device has just been placed on the market. It is intended as a production instrument for making simultaneous and instantaneous commercial tests for all electrical defects and their locations in armatures and bare commutator in distinction to the present step by step methods which frequently involves hundreds of distinct

tests on the same armature. It is claimed that the armeter will indicate whether an armature is o.k. or if not will reveal such defects as: open circuits and where; bad joints (on coarse windings) and where; short circuits between sections and which; short circuited windings and where; mixed connections and how mixed; irregular number of turns and whether high or low; grounds; tests made at substantial potential, not micro voltages usually used; also instantaneous tests of all sections of a bare commutator for both short circuits and grounds.

Its tests are claimed to be superior tests for it is said to indicate defects that only show up in bad behaviour after running a while. To test an armature its commutator is slipped into the circle of contact fingers in the centre whereupon the circle of small lamps one for each section which are used for indicators will on normal armatures burn as with half voltage, on short circuits light up more or less bright, on open circuits extinguish. Bad joints (on coarse windings) and excess turns are indicated by dimness, other defects by other irregularities. A ground detector operates simultaneously. Lamps are used for indicators as their indications command attention better than eye straining needles. A pilot lamp indicates their correct reading. The entire device is said to be strong and durable and to have no delicate parts and no moving parts except contact fingers. It is a production instrument not adjustable, but will also indicate shorts in higher voltage winding and open circuits on lower voltage windings at equal speed. It is manufactured by P. E. Chapman, St. Louis, Mo.

SAW SHARPENING MACHINE

A saw sharpening machine intended for sharpening circular saws from one and one half to 8in. in diameter has been placed on the market recently. It is particularly adapted to sharpening circular metal saws, screw slotting cutters and jewellers' saws. Saws up to 5/32in. thick and having holes from ⅜ to 1in. can be handled. The indexing is accomplished by means of the saw itself. The machine will likewise take care of saws with broken teeth. The grinding wheel is 4½in. in dia. by ⅜in. thick. Adjustment for wear is provided in the grinding spindles by means of a tapered bearing. The net weight of the machine is about 135 pounds and is manufactured by George Sherr, 126 Liberty St., New York.

JACKS, BLOCKS AND T-SLOT NUT

A recent development in small machine tool jacks has recently been placed on the market. These jacks are made in sections so that any required height can be obtained. They have a small point at one end and are flat on the other so that either end may be placed against the work as desired. The screw portion has a movement of ⅜in. and the pitch is fine enough to prevent it from running down under the pressure of the work. The height adjustment of the jack is obtained by means of tubular extension blocks. The tubing is made of 2⅜in. diameter stock and ranges in length from 1, 2¼, 4¾ and 9¼ inches. Another development of this firm is in the form of a T-slot nut, especially designed for putting additional clamps on machine work while on the table. The nut can be slid along the slot to the desired position and the stud or bolt with its clamp can be inserted from above. In this way additional bolts can be applied without disturbing the work. In this way clamping equipment can be reduced by the fact that bolts of any length can be inserted in the nut. These nuts can be furnished in any size desired Both jacks and T-slot nuts are manufactured by the Marvin & Caster Co., Canastota, N. Y.

BOOKLET

The Canadian Ingersoll-Rand Co., Montreal, has recently issued a new catalogue phamphlet on air receivers pressure tanks, moisture traps and aftercoolers. It is listed as Form K310-A.

Keep The Standard High

OUR REMARKS in the May 25 issue regarding the proposed Engineers' Bill have been taken in some quarters to indicate lack of sympathy on our part with the suggested measure. Such is far from being a correct interpretation of our ideas. Our criticism of the suggested measure was based solely upon our desire, in the interests of the engineering profession, to ensure that such a measure should be workable and of such a character that no reasonable person could with justice raise any objection to it. The fact that objections were raised immediately upon the bill's introduction shows that careful consideration was necessary. The bill has now been passed, but minus the clauses we already referred to.

Both for the protection of the public and in the interests of the engineering profession, it is highly desirable that the latter be given a status which would be a guarantee that a duly registered member was competent to perform work entrusted to him; but to load the bill with penal clauses which might conceivably result in a thoroughly competent man being heavily fined and forced out of business because for some reason or other he might not see his way to become a member of the official organization, is hardly fair or wise.

A proposition of a nature still more detrimental to the interests of those proposing it, has just been launched by the plumbers of Montreal, who, professedly in the interests of the public, ask the city authorities to increase the master plumber's fee from $5 to $200 per annum. This they claim would eliminate the non-competent men from the craft. The weakness of this argument is apparent from the very fact that the men referred to would be in no way debarred from continuing their careers of incompetency provided they could raise the sum of $200, and also when it is seen that no matter how competent a man might be it would be impossible for him to obtain a license to carry on his trade if he could not find that sum. If incompetent men are giving the trade a bad name the obvious remedy is to make the examination they are called upon to pass more severe.

It is a laudable desire on the part of any trade or profession to raise the ability of its members to as high a standard as possible, but this object can not be attained by enacting penal measures which might inflict injustice upon fully competent persons legally engaged in that line.

Let the engineers organize, making their examination as rigid as they wish. They could then issue a certificate of merit to those found competent, which certificate would serve as a guarantee of proficiency to anyone engaging their services. The maintenance by the organization of a high standard of efficiency for its members would inevitably result in eventually weeding out all those who were inefficient, for the knowledge that membership was regarded by the public as a certificate of competency would soon induce all good men to become members.

How Will Improved Demand Affect Prices?

IN A RECENT editorial we referred to the distinct signs of improvement in the outlook for business generally which have lately been in evidence throughout the country. There are not lacking indications for an improved demand for all kinds of manufactured goods, and in some quarters it is taken for granted that with improved demand will come a rise in prices. It is worth while considering how far this anticipation is justified.

In discussing price fluctuations reference is frequently made to the so-called law of supply and demand and it is assumed that prices vary upwards or downwards as the demand increases or decreases. This assumption however presupposes a stable level of prices. When production is steady and prices have only fluctuated within narow limits for a considerable period as was the case in 1913, an increase in demand which necessitates the employment of fresh capital, the extension of manufacturing plants, and the employment of extra labor, will probably result in a rise in prices, at any rate temporarily. On the other hand, a lessening demand resulting in the closing down of works and the accumulation of stocks will produce a contrary effect.

At the present time however we must bear in mind the important fact that it is not yet established that industrial prices have yet reached a stable level. They are roughly speaking on an average some fifty per cent. higher than they were in 1913, and therefore it is quite possible and even probable that they have not yet done so, but that there is a further drop in store for them before stability is reached. There are to-day many factories and plants which are not working at anything like capacity, unemployment to a more or less extent is prevalent in most lines, and till demand increases is likely to remain so.

Under these circumstances a revival in demand is not likely to cause a general increase in prices. The idle plant and machinery is at hand to increase output in response to the new demand for goods when it comes; and therefore increased demand simply means a fuller employment of labor and a more complete utilization of materials, plant and machinery. Supply will be kept equal to demand at the same price. It is even possible that increased output might result in decreased overhead costs and competition might bring about reduced prices if such reductions were thought likely to attract buyers.

The point we wish to emphasize then is that a revival in demand and an improvement in conditions generally, although of course it might cause temporary fluctuations, does not necessarily imply increased prices.

Among the articles scheduled for coming issues are: Hints to the Operator in Setting Up Planer Work, June 22; Value of Keeping a Product Clean, June 29.

Several Lines Show Advancement In Prices

Steel Market Firm and Business Moving at Good Rate—Pig Iron Quiet—Non-Ferrous Metals Slightly Stronger—Machine Tools Show No Change—Supplies Improve in Demand.

STEEL PRICES GO UP IN SOME LINES

THE Canadian iron and steel market shows good strength. Several advances in prices have taken place in the Toronto field this week. Bars now range between 2.90c to 3.00c in place of 2.75c and sheets, including blue annealed, black and galvanized, have all gone up a little. Black sheets were $4.40 and are now $5.00; blue annealed were $3.75 and are now $4.00; galvanized were $5.60 and are now $6.00. Added strength, recent advances in the States, and steady demand are factors in these increases.

Cotton twine has also advanced 3 cents per pound.

Pig iron remains steady and the demand has not changed over the week.

Some non-ferrous metals show added strength, copper featuring. Prices are firmer and consumers seem to be taking more interest in the market, especially in Toronto locality.

Scrap metals are holding their own showing a little added strength in some lines. Cast iron is strongest.

The demand for small tools and supplies is slightly improved over last week. According to figures secured up to date of writing, June sales will be ahead of last month. Enquiries are better in these lines.

Machine tools are selling at about the same rate. Competition is still keen and dealers follow up everything that looks like an order very thoroughly. Enquiries are encouraging and while the amount of sales closed has not been very large, dealers are by no means discouraged. They feel an improvement is under way.

Oils and waste are in good demand, while steel pipe is very firm. Prices in the latter mentioned line are strong and deliveries extended. Boiler tubes are rather quiet and prices remain unchanged.

The official report of steel production in the United States in 1921, has now been issued and following are some of the chief points of interest. Steel ingot production was less than half the figure existing in 1916, 1917, 1918 or 1920. In fact, with the exception of 1908 it was the lowest rate since 1904.

Structural shapes showed a sharp decline the tonnage being the smallest since 1908. Black sheets, 13 gauge and lighter did fairly well, the production being greater than any year prior to 1910. Steel castings showed quite a reduction, viz. 559,713 tons against 1,251-542 tons in 1920.

Production of steel ingots was about 37 per cent. of capacity or 44 per cent. of record figures. However, large additions to capacity have been made since 1917 for in 1912-13, about 30,000,000 tons was capacity against approximately 55,000,000 at the present time.

Steel ingot production in May, 1922, showed an increase over the April, 1922 figures. The mills seem well fortified for a continuance of present rate, with exception of July and August, which are usually dull. Although the turnover is lighter, the steel market is very strong.

First sales of Lake Superior iron for season of 1922 have occurred, the price being 50 cents lower than 1921 schedule. The pig iron market remains stagnant.

Toronto

June 14

SEVERAL interesting developments have taken place during the past seven days. We warned our readers last week, that the price on iron and steel bars would be firm at 2.90c in place of 2.75c and the truth of our remarks is very evident when we can now report a firm market in bars at between 2.90c and 3.00c. Those who took our advice and purchased their metal at 2.75c, the old figure obtainable last week, are that much to the good.

Steel has also advanced in price, the new quotations being shown in the tables below. All these increases have been threatening for some time, because the steel market in the United States has been very firm. Canadian markets always reflect conditions over there, and these changes would have occurred before, had not competition been so keen.

Iron and Steel— In all iron and steel lines, the demand is firm. Building activity keeps up, therefore the demand for reinforcing bars, hardware, sheets, and other kindred lines used in construction work, is still good. Nothing is featued but the tone is good and prices firm. When we stated previously that quotations on iron and steel bars range from 2.90c to 3.00c, we infer that the fairly large user can get the lower figure, while the ordinary consumer usually pays the 3.00c price. However, if you are in the habit of placing all your business with one house, you have a chance at the lower figure. Band steel, of course, automatically goes up with bars.

Iron bars	2 90	3 00
Steel bars	2 90	3 00
Reinforcing bars	2 90	3 00
Steel hops		4 00
Tire steel		3 15
Spring steel		6 00
Band steel, No. 10 gauge and 3-16 in base		3 50
Small shapes		3 00
Sheets, black, No. 28		5 00
Sheets, blue ann., No. 10		4 00
Canada plates, dull, 52 sheets		6 00
Canada plates, all bright		
Galvanized Sheets, No. 28		6 00

Pig Iron.—There is no change in this field. The price is still $27.15 and the demand is as steady as can be expected, considering present foundry activity.

Non-Ferrous Metals— Copper shows more life than at any time during this year. Consumers are at last realizing this market is low, with a possibility of higher prices and are displaying more interest at present quotations. However, there seems to be lots of metal on the market and prices while firm, have not advanced as yet.

Red brass also shows strength, but not the same as in the copper field. The demand is not so strong but prices are fairly firm. Yellow brass is a little stronger owing to enquiries from the United States, but it has a long way to go yet. Following are quotations:—

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals—Yellow brass turnings are in fair demand, while cast iron scrap is firm. Steel has receded a little, but turnings of both the above mentioned metals are in fairly good demand. Prices are steady.

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools—There is no change in the demand for machine tools. Any orders being closed are for small amounts, but the total of sales is by no means discouraging. Every dealer displays confidence and feels that although the present improvement is slow, it is bound to come stronger after a while. In the meantime they are going after everything that looks like an order in a very thorough manner. Enquiries are better and keen competition still exists.

Small Tools and Supplies— Business has been fairly good over the week, and an improvement over our last report. One merchant has taken another line, this being reported in the industrial news section on another page of this is-

sue. The demand is coming from all quarters and is very varied. The total sales for June should be well ahead of May, according to reports received up to date of writing.

Oils and Waste—Oils are unchanged in price and demand. Waste is selling at a steady rate, and cotton twine has advanced 3 cents per pound. In other words, 4 ply cotton twine sold in cones was 36c and is now 39c. This change took effect June 12. All other plys went up in the same proportion. Following are quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	10 80
Pure turp., single bbls. gal.	1 40
Linseed oil, raw, single bbls.	1 15

WASTE

XXX Extra	16	Atlas	13
Peerless	21	X Empire	13
XX Grand	15	Ideal	13
Superior	20	X Press	11½
X L C R	14		

Colored

Lion	12	Fancy	13½

No. 1	13	Keen	7½

Wool Packing

Arrow	30	Anvil	20
Axle	25		

Washed Wipers

Select White	18	Dark colored	18
Mixed colored	14		

Steel Pipes—A very firm market still holds good. Deliveries are getting slower all the time and prices are decidedly strong. Boiler tubes are still the same, existing figures being shown on the quotation pages.

Montreal

June 14

BUSINESS in the iron and steel lines for the past week has been without any outstanding features. The volume of trade is quite as large as that of the previous week, and in some instances it shows an increase. Announcements from one or two of the larger manufacturing concerns of plans for increased activity in the near future, has created a little more optimism in some lines. The building activity is still very marked. Few large contracts have been let lately but there appears to be no diminishing in the numbers of smaller jobs. This work creates a demand for varied small lines of steel.

No prices have been changed during the past week. Pig iron is steady at $31.80. Machine tools are very sluggish, while supplies are moving about the same as usual. Non-ferrous metals are firm, while the sales keep moving at about the same level. The scrap metal market is quiet.

Iron and Steel— Local jobbers state business has been slightly better than last week. The base price of steel is quoted as $2.90, but it is felt that attractive business can obtain a lower figure. The mills are quoting the jobber and the large consumer $2.50 and $2.30 base, respectively.

Galvanized sheets are moving fairly strong. Black and blue annealed sheets are also in demand. The large amount of building is to a certain extent responsible for this demand and screws, bolts and other small steel products, are also being required in fair quantities for the same reason. Merchant bars and plates are very quiet locally. Structural steel is called for in small quantities. There is no indication from the railways as to their probable entry into the market for rails and other steel products.

Keen competition is in evidence, as all orders are very aggressively sought. Even large jobbers go after the smallest orders. Quotations are:

Iron bars	2 90
Steel bars	2 90
Reinforcing bars	2 90
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron—The quiet tone of the pig iron market for the last two weeks remains unchanged. No. 1 iron remains at $31.80. The fact that Summerlee iron is still making its appearance in small quantities is creating a great deal of attention from Canadian producers. Just what effect this will have is not known. Sales are very small as foundries are only purchasing enough to take care of their immediate needs. For that reason it not thought that the matter is being as seriously considered, as if business were normal.

Machine Tools—The sales reported for the week are all for small machines. Several dealers state that there has been a very decided increase in the number of inquiries received. One dealer has a prospect for a couple of large machines, and wood working tools are in a little better demand than the iron working machines. No recent price changes have been made. Sales for 1922 are slightly in excess of sales for 1921.

Machine Shop Supplies—A large number of the shops are engaged in jobbing and contract lines are working nearly to capacity. Railway shops are working a number of men, and thus, the small tool trade keeps up very good. Business is somewhat spotty, but is generally improving.

Non-Ferrous Metals—A firmer tone is evident in the non-ferrous metal market especially in the case of copper. There is only a nominal improvement in sales and nearly all the firmness can be traced to foreign markets. Local dealers are disappointed in the volume of sales and stocks of metals are down rather low compared even with pre-war stocks. The demand is so light that dealers have not considered it profitable to carry large stocks. Local quotations are:—

Lake Copper	17 50
Electric Copper	17 25
Castings, Copper	17 00
Tin	35.50
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metals—Quotations on scrap metals are up rather high owing to the increasing demand in Pittsburg and New England areas. Business is improving to a slight extent but the foundries are still very quiet and until they commence to operate at a greater capacity, little business will be done. The holdings of local dealers are small. Prices quoted are:

Copper, light per 100 lbs.	9 50
Copper, Crucible	13 00
Copper, heavy	13 00
Copper Wire	13 00
No. 1 composition	10 00
New brass cuttings	7 50
Red brass turnings	8 00
Yellow brass turnings	5 25
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	13 50
Boiler plate, per gross ton.	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable	10 00
No. 1 machine cast iron	23 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	19 00
Mach. shop turnings	4 00
Stove plate	19 00
Cast boring	3 50

Pittsburg

June 14

THE official report of steel production in 1921, issued in the past week, shows steel ingot production to have been 19,184,084 gross tons, or just a shade under the estimate given in this correspondence at the close of the year. The production was less than half the amount in 1916, 1917, 1918 and 1920, while with the exception of 1908, it was the smallest since 1904.

Production of finished rolled steel was 14,228,329 gross tons, or 74 per cent of the ingot tonnage, the usual proportion being 75 or 76 per cent. The lower figure was presumably due to there being a smaller percentage than usual of heavy rolled products, which involve less scrap in their manufacture. The loss between ingot and finished rolled steel is chiefly in scale, which goes back to the blast furnace for reworking, and scrap, which goes to the open-hearth furnace.

Structural Shapes.—The greatest set back in production was in structural shapes, the 1,272,624 tons being the smallest since 1908. The trade had been prepared for this by the reports during the year, showing that lettings of fabricated steel contracts represented only 35 per cent. of fabricating sop capacity. Black sheets, 13 gauge and lighter, did relatively well, the 1,367,688 tons produced being greater than in any year prior to 1910.

Production of steel castings in 1921 was 559,713 tons, against 1,551,407 tons in 1917, the record year, and 1,251,542 tons in 1920. Production of steel ingots in 1921 was 44 per cent of the record production, made in 1917, while it was about 37 per cent. of capacity. There have been large additions to capacity since 1917, as even the production of that year did not represent capacity. There were plenty of orders, but there was physical disability, including shortage of transportation, and shortage of labor. In fact, the steel industry has been under a new alignment with in-

dustrial and general conditions in the country since November, 1916, for prior to that time, with the exception of the winter of 1902-3, when there was railroad congestion, the steel industry was always able to operate at capacity when it had the orders, while since then it has never operated at capacity, though at times it had plenty of orders, there being labor shortage, strikes, insufficiency of transportation, etc.

It is time to recognize this new alignment and consider the consequences. Seeing that in 1912 and 1913 the industry made about 30,000,000 tons of ingots, and in only one previous year as much as 25,000,000 tons, the industry of late, with a capacity about half-way between 50,000,000 and 55,000,000 tons, has seemed altogether too big. It appeared that orders for such tonnage of steel would be difficult, if not impossible, to secure. The broader view is that the industry is so large, by comparison with the size of the country, for the census returns showed only 9 per cent. increase in the number of persons "gainfully occupied" from 1910 to 1920, that there are several possible limitations to its operation, including the matters of orders, supplies of raw material, transportation, and labor available.

Just now the limiting factor to operation that is visible is the coal strike, but if the coal strike were suddenly terminated the industry would hardly be able to secure enough labor for full operation, and it is rather probable that the railroads would be unable to haul all the freight offered. To consume a tonnage of steel equal to the steel industry's capacity would also be impossible, for while the requirements might possibly be gathered up, men could not be found to do the requisite work in fabricating or using the steel. In other words, the country can be very busy, with everybody employed, and the railroads fully occupied, without the steel industry running at its capacity, and so the much quoted steel making capacity is largely a dead letter.

The important point which will affect steel prices, is which will get busy up to the limit first, the steel producers or steel consumers. Dependent upon this fact, we will have a sellers', or buyers' market. Of late there has been a sellers' market, and so far this condition continues.

Steel ingot production in May was at about 38,250,000 tons a year, showing a further increase over the 35,000,000 ton rate obtained April 1, when the coal strike began. The steel mills seem well fortified for a continuance of their present rate of production, except for the usual decrease that occurs in July and August on account of weather conditions.

The coal strike, both regular union, and nonunion part, in the Connellsville region, Westmoreland County, etc., has gone along without incident until a few days ago, when the Pittsburgh district operators sent another invitation to the miners' local organization for a wage scale conference, the invitation being promptly refused. The operators insist that they will not again make a four-state agreement, while the miners insist they will negotiate for nothing else. The presumption is that the Pittsburgh operators renewed their formal offer for the purpose of putting the miners on record again, preparatory to the operators making an effort to operate some of the mines, and important developments may occur in the next week or two.

The steel market is very strong, although the turnover is lighter than in April, mills being comfortably sold up, while most buyers are well covered. A few buyers are not, and there are new wants arising, so that some business is done. This shows the market to be in even stronger position than two or three weeks ago, and in several products there is a range of prices, mills having the lowest prices being willing to sell only to regular customers, and only when the steel is for a specific job. Other buyers must go elsewhere and pay higher prices.

The market is quotable as follows: Bars, shapes and plates, 1.60c to 1.80c; hoops and bands, 2.25c; to 2.50c; blue annealed sheets, 2.40c to 2.50c; black sheets, 3.15c to 3.40c; galvanized sheets, 4.15c to 4.40c; automobile sheets, 4.50c to 4.75c; standard steel pipe, 71 per cent basing discount; wire nails, $2.40 to $2.50; tin plate, $4.75

First sales of Lake Superior iron ore for the season of 1922 occurred June 9, establishing a market, f. o. b. Lake Erie docks, 50 cents below the 1921 schedule, which by a reduction of $1, had represented a return to 1919 prices. The new quotations are: Old range Bessemer, $5.95; non-Bessemer, $5.20; Mesabi Bessemer, $5.70; Mesabi non-Bessemer, $5.05. Prices are based on 55 per cent. iron content in Bessemer ores and 51½ per cent. in non-Bessemer ores. Naming of prices was delayed this year, by the slowness of inquiry and by waiting in the Interstate Commerce Commission to settle the upper lake rail case, where the ore interests requested a reduction of 25 cents. It is assumed that the reduction will be made, and as the lake vessel rate has been reduced 10 cents from 1921, making it 84 cents from the head of the lakes (including the 14-cent dock charge) there is left 15 cents for the ore interests to absorb in the total reduction of 50 cents at Lake Erie docks.

The pig iron market remains stagnant, quotable prices, now largely nominal, continuing at $25 for Bessemer and basic and $24 to $25 for foundry, f. o. b. valley furnaces.

PROPER LIGHTING OF WORKSHOPS

So important is proper lighting in connection with industrial plants that the widespread negligence still observable is a reproach to intelligence. In some cases the remedy attempted is an aggravation of the evil, local or individual lighting, for instance, being so placed that its dazzling effect injures the worker and handicaps the output. Bad lighting is a visible sign of bad management, because it creates a manifest and needless loss. This is a matter not of theory but of close investigation by competent observers, whose conclusions agree with what one may term the common-sense view of the case. In many cases it has been found that a simple yet effective improvement has produced better lighting at a lower cost than the faulty original. Good lighting has the power to stimulate, and stimulation in the workshop is doubly useful by increasing production and lessening error.

LARGE FRICTION WINCH

There was recently built in Great Britain, and for one of the British Dominions, a steam winch of unusual power. This winch has three drums and is designed to hoist a total load of six tons at a speed of 200 ft. per minute. It has three barrels mounted loosely on shafts and engaging with them through friction clutches. The load may be hoisted on any one of the barrels or distributed among the three barrels. Further, while one or two of the barrels are in use for hoisting purposes, the other or others may hold suspended a load up to six tons. The winch is driven by a two-cylinder engine and it will be used on a large harbour.

GREAT BRITAIN AND HYDRO-ELECTRICS

During recent years more than one of the large electrical manufacturing groups in Great Britain has organized itself to carry out hydro-electric schemes on a large scale. The latest development is the formation by one of the leading armament and engineering firms of a special department to deal with complete water power development schemes in all their aspects, civil, mechanical, and electrical. This great firm is at present carrying out surveys, in many parts of the world, of schemes brought before it and considered by a powerful financial group with which it is working in conjunction.

IMPERIAL AIRSHIP SCHEME

Strong support is being given by industrial interests in Great Britain to the scheme for establishing a commercial airship service between Britain, India, and Australia. It is confidently expected that the British Air Ministry will recommend the Government to assist this enterprise, for which detailed and promising estimates have been drawn up. Meanwhile the speed of British air services to and from France is increasing. Recently a record was established by a British machine on which four successive single trips between London and Paris were made in the interval between 6.55 a.m. and 5.40 p.m. Out of 10¾ hours between the first ascent and the last descent 8 hours, 52 minutes were actually spent in the air. The total distance covered was about one thousand miles.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

News From the Industrial Field

An electric lighting plant may soon be installed by the Chipman Flour Mills Co., Chipman, Alta.

Factory burned.—The Muskoka Wood Mfg. Co. factory and mill at Huntsville has been destroyed by fire.

Will construct dam.—The Pacific Pulp Mills Co., Ocean Falls, B.C., will possibly erect dam at cost approximately $500,000.

Will erect plant.—The Cape Breton Cold Storage Co. will erect a plant at North Sydney, N.S. The cost will be around $200,000.

May erect theatre.—Mark Rodgers, Lethbridge, Alta., is contemplating the erection of a theatre at Cranbrooke, B. C. $12,000 is the estimated cost.

It is a good plan to wash out machine bearings from time to time with gasoline as they frequently become stiff from gradual accumulation of fine particles of dust.

Montreal, Que.—Tenders have been called by the city executive committee for the construction of a filtered water reservoir at Atwater Ave. water works. The estimated cost is $500,000.

Recreation Club planned.—F. J. Gallanough, architect, 79 Albany Ave, Toronto, has plans for a recreation club for Riverdale Recreation and Athletic Club Ltd.

Addition to plant.—Stanfields Ltd., Truro, N.S., will add to present plant. Russell & MacAuley, 10 Walker St., Halifax, has the contract, and the addition will cost approximately $125,000.

Sub-contracts have not been let as yet for the following equipment in the Mount Royal Hotel, Montreal. Kitchen equipment, ice plant, refrigerators, and pneumatic tubes. Thompson Starrett & Co. are general contractors.

J. H. Grant & Co., Montreal, have been awarded contract for construction of rod rolling mill and electrical substation for Eugene F. Phillips Electrical Works, Brockville, Ont.

A transformer Sub-station for the Hydro-Electric Power Commission of Ontario will soon be erected at Chatham, Ont. E. B. Lawler, district engineer, has completed the plans.

Shawinigan Falls, Quebec.—The Belgian Industrial Company now has orders which will keep its plant running all the year at full capacity. It is stated that it is not able to fill all the orders it is receiving and it has started on a new extension to accommodate two more paper machines, one of which will be ready about January next year, the other in July.

Bridge Being Erected.—The C. P. R. bridge at Coquitlam, B.C., which was washed away by floods last year is now being replaced. The new structure will cost $172,000, and goes over the Coquitlam river.

Port Arthur, Ont.—An arena costing $7,500 will be erected in Current River Park. A public school on Prospect Ave. to cost $200,000 will also be built. Those interested can write city clerk T. F. Milne.

Industrial conditions in Peterboro show signs of improvement owing to the increased outside work now going on. Many manufacturing plants are adding to their staffs. Some mechanics have gone to Oshawa and Windsor to engage in motor factories.

New Station.—Galt will soon have a new station. M. W. Kirkwood, general manager of the G. R. R. and L. E. & N. Ry., has received revised plans for the new depot which will be erected on Main Street.

Ottawa, Ont.—W. E. Campbell, lately freight expert advising the Government Railways Department and the Railway Commission, has been appointed Chief Traffic Officer for the Dominion, succeeding the late James Hardwell.

Will build garage.—Plans are now prepared for a garage for W. H. Muckle, 88 Adelaide St., Toronto. E. J. Hunt Stanford & Sons, architects, 67 Yonge Arcade, have the plans. The estimated cost is $21,000.

P. J. Pybus, managing director of the English Electric Co., and John Sampson, of John Brown & Co., the English shipbuilders, are at present in Canada. They will inspect the plant of the English Electric Co. of Canada at St. Catharines while they are here.

Will erect hospital.—Plans have been prepared, and tenders are now being received for the erection of an hospital at Wallaceburg, Ont., which will cost about $50,000. Chester Wood, 217½ Christina Ave. N., Sarnia, Ont., is the architect.

Fire Causes Damage.—Fire on the premises of the St. John Drydock & Shipbuilding Co., N.B., destroyed the roundhouse and one locomotive, a building owned by the Bedford Construction Co., also a compression outfit owned by the Drydock company and stores valued at $20,000. The loss was $30,000.

The Engineering Equipment Co., Ltd., Montreal, have been appointed exclusive Canadian sales representatives for Schutte & Koerting Co., of Philadelphia, manufacturers of low level jet condensers and other power plant equipment.

Construction work.—Stratford, Ont.—The latest building figures are most encouraging, showing that construction work was greater in the last five months than in any entire year of the past twelve years. Forty-one permits for dwellings during May were issued, as against fourteen for the same month last year.

Addition to Factory.—The Gardner Construction Co., Welland, Ont., has been awarded contract for erection of $72,000 addition to factory of Empire Cotton Mills. When the building is completed, machinery installed and warehouses added, the total cost will be about $215,000.

Additional contracts for alterations to bank costing $35,000 for Royal Bank of Canada, at Winnipeg, Man., are: Electrical, Levy Elec. Co. Ltd., Portage Ave.; plumbing and heating, Standard Plumbing & Heating Co., Fort St.; plastering, Western Plastering Co., Confederation Life Bldg. Sutherland Construction Co., general contractors, Merchants Bank Bldg.

An analysis of the report indicates that a state of stability has been reached in the price situation, advances in one group being offset by recessions in another. The fact, however, that the average price level is now much higher than that which existed immediately prior to the war, is regarded by economists as an indication that rock-bottom has not yet been reached.

A Canadian Chapter has been formed of the American Association of Heating and Ventilating Engineers, to be known as the "Canadian Division, Ontario Chapter." The membership is at present about 35, the first meeting was held June 2, when the following officers were appointed:—M. H. Thomas, president; H. H. Angus, vice-president; A. S. Leitch, secretary, and A. J. Dickey, treasurer. Monthly meetings will be held in Toronto.

Fixed assessment.—Weston, Ont.—The Canada Cycle & Motor Co. have been granted a fixed assessment as follows:—$60,000 for the first five years; $70,000 for the second five years, and $80,000 for the third five years. There is one provision made, and that is that the company, are by a special by-law, brought within the town limits. At present the company are just located outside the town limits. Representatives of the Ford Motor Car Co. have asked the Weston council to close a portion of Rosemount avenue, between Dufferin and McDonald avenues, in the event of their locating near there. The council agreed to the closing of the specified area, if the company follow out their plans.

Quebec, Que.—It is anticipated by local shipping men that the volume of business on the harbor front this year will exceed that of the record year, 1921. Many new improvements are being made by the Harbor Commission to accommodate the new freight and passenger steamers, which have included Quebec on their calling list for the first time.

Montreal.—Mr. Arthur H. Sancton, late of Messrs. Fraser & Chalmers of Canada and consulting mechanical engineer for the Hollinger and McIntyre Gold Mines of Timmins, Ont., is in charge of the new industrial manufacturing department that is being organized at Canadian Vickers Ltd. Contracts are being negotiated for the firm to manufacture some lines of heavy machinery. These deals concern both United States and British firms.

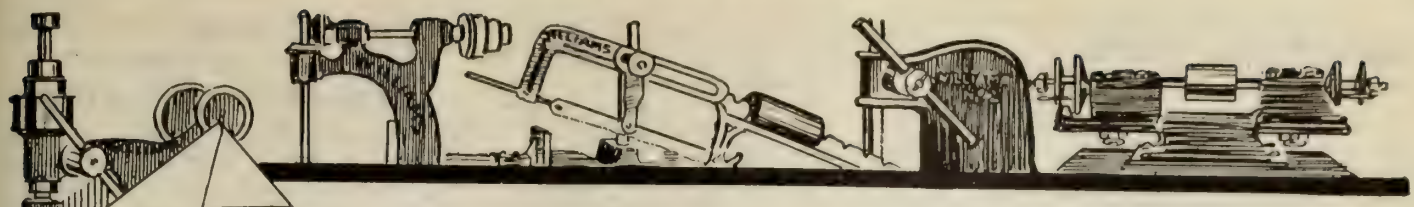
Tenders Wanted.—Tenders are being called for several pieces of construction in Alberta by the Canadian National Railway. A connection between the Canadian Northern and the Grand Trunk Pacific at Magnolia, a distance of .83 miles; a connection between Bashaw and Battle River subdivisions, 3.47 miles long, near Camrose, and a connection at Ryley, 1.83 miles long, between the Viking and Battle River subdivisions are to be constructed. Plans and specifications may be seen at the office of the district engineer in Edmonton and the division engineer in Calgary.

Shop is busy.—Montreal, P. Q.—J. R. Parkes, general manager of the Stowell Screw Co., Longueuil, states that his firm has been able to obtain sufficient orders to keep them operating practically at normal capacity all through the period of depression. During the last two months, his ordinary business has been improving steadily, and in addition the firm has received a large number of very attractive orders for small screws to be used in the manufacture of parts for radio apparatus. The plant is very busy in an effort to keep pace with orders that are coming in daily.

Have secured contracts.—Contracts for four 54-in. pumps which are to be installed at the Sumas dam, to drain Sumas Lake, B.C., have been awarded to the Dominion Engineering Works, Ltd., Montreal, by the B. C. Land Settlement Board. The pumps, which have a capacity of 750 second ft., are driven by individual motors, which will be of approximately 600 and 1,200 h.p., two of each being installed. The contract was let through C. A. Yowill, of Vancouver, and delivery is promised for February, 1923.

Have Purchased Plant.—The Premier Paper & Power Co., recently incorporated, have purchased the H. Croix Paper & Lumber Co., acquiring the latter's watershed and 26,000 acres of pulp land. They are planning the early construction of a new paper mill and power plant to cost approximately $1,500,000, states Phil H. Moore, managing director of the new concern, whose office is at 91 Hollis St., Halifax. The mill will be 35 miles from Halifax, and will consist of two hydraulic turbines generating approximately 3,300 h.p., four water wheels to drive grinders, and one newsprint machine. Contract for construction of the mill may be let upon a cost-plus basis, although nothing definite is set as yet. Geo. F. Hardy, of New York, is consulting engineer.

Orders Will Be Placed.—The Metachewan Power Co. have announced their board of directors. Following are those interested:—President, Robert Fennell, Toronto; 1st vice-president, F. J. Westaway, Hamilton; 2nd vice-president, Col. Robert Stark, Montreal; D. W. Caldwell, Perth; Sir Henry Galway, D.S.O., London, Eng.; and H. W. Sutcliffe, New Liskeard. The completed plant will produce 13,000 h.p., and supply power to the Kirkland Lake, Elk Lake, Gowganda and Shining Tree mining camps. The company, which is capitalized at $1,000,000, has the power rights on the Indian Chutes and Big Ben, on Montreal River. Work has already commenced and orders for machinery will be placed at once.



Sault Ste. Marie.—The movement of freight through the canals here during the first full month of navigation ending May 31, aggregated 3,316,645 short tons, according to a report compiled for the United States Engineer's office here. This is a decrease of 2,828,418 tons, compared with the movement in similar month a year ago. The movement of wheat, downbound, aggregated 24,662,396 bushels against 12,609,469 bushels a year ago, and that of other grains was 26,734,772 bushels, compared with 12,429,593 bushels in May last year. The movement of wheat and other grains was about normal. Iron ore, downbound, totalled 1,379,850 short tons, and copper shipments were 5,898 short tons. Ore cargoes a year ago totalled 2,647,833 tons. Coal shipments to the north were 203,988 short tons of bituminous and 2,100 short tons of anthracite. In May last year the movement of coal was 2,220,000 tons. Vessel passages numbered 1,305, compared with 1,515 a year ago.

The late Minister of Marine and Fisheries, the Hon. C. C. Ballantyne, has been elected a director and president of The National Brick Co., of Laprairie, P.Q. Although a number of the directors and large shareholders of the company desired to see Mr. Ballantyne occupy the president's chair, he was finally influenced in his decision by the wishes of T. A. Trenholme Estate. The former president of the company, Mr. H. R. Trenholme, who is also an executor of the Trenholme Estate, retired owing to private business pressure. Mr. Ballantyne is well known throughout the country, and is a director of the Royal Trust Co., Canada Cement Co., Montreal, Locomotive Works, The Canadian Explosives, Ltd., and for many years was vice-president and managing director of The Sherwin Williams Co. of Canada.

Enquiries are encouraging.—Montreal, P.Q.—Mr. P. L. Miller, general manager of Canadian Vickers Ltd., states that inquiries for the Sea Sled, the new type of motor boat the company is manufacturing under the Hickman Patents, have come not only from all over Canada, but from points as far away as South America. The number of inquiries is very encouraging, as many of the prospective purchasers plan to place the boats in commercial work. Mr. Miller confirmed the rumor that the large sea sled now being built at the plant, would likely be run up the Lachine Rapids, to test its ability to navigate in turbulent waters. The company have secured selling rights for four of the adjacent New England States, and if business warrants, will probably erect a small plant on Lake Champlain to build these boats.

Following are several companies recently incorporated:—Bouret, Ltd., with head office at Quebec, and a capital of $20,000. They will carry on a general contracting business. The United Building Corporation, with head office at Toronto, capital $60,000, to carry on a contracting business. The Heath Unit Tile Co., with head office at Toronto, with a capital of $50,000, to manufacture and deal in clay products and builders' supplies. E. O. Leahey & Co., head office at Ottawa, with capital of $150,000, to carry on the business of general contractors and to deal in building materials. Coland Construction Co. head office at Toronto, with capital of $40,000, to carry on an engineering and contracting business.

Will build iron plant.—The British Steel Corp. has undertaken to construct in Newfoundland before 1928, a plant capable of producing 100,000 tons of pig iron annually. This action is taken following an agreement between the Corporation and the Newfoundland Government, the latter having arranged to pay a royalty of 25 cents per long ton to the British Empire Steel Co. for every ton of ore that is mined in the Colony. The Steel Corp. further undertakes to erect coke ovens, and to expend $3,000,000 in Newfoundland before 1926. It has been arranged that raw materials to be used in the construction of these plants are to be admitted to the island free of duty. Both subsidiary companies of the British Empire Steel Co.—The Dominion and Scotia—are granted rights regarding tax exemptions and water power grants. The royalty of 25 cents per long ton is to continue in force until December, 1940. In the event of either company failing to carry out the construction programme agreed upon, or should they fail to expend $3,000,000 in Newfoundland before 1926, an export tax of $1 per ton will be imposed by the Newfoundland Government upon all ore mined and shipped to any part of the world except Nova Scotia.

What's a Guarantee Worth?

YOU don't buy machinery without a guarantee—of course not; yet—and it's worth a thought—no firm's guarantee can be worth more than the value that firm places upon its prestige.

The Williams Guarantee is part of the unusual Service we offer. We do not consider any transaction concluded until you are completely satisfied. Even after that our experts are at your command to advise and co-operate in any problems that may arise. And this guarantee backs every sale whether of new or re-manufactured tools.

Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

MONTREAL TORONTO WINNIPEG

-A Small Heavy Duty Lathe
-With 32 Thread Changes
THE
ROCKFORD
"ECONOMY"

This double back geared, quick change engine lathe brings many advantages to the tool room. High grade, accurate, small in size but extremely powerful.

All gears are cut steel and covered to safe-guard the operator. A lead screw is used only for chasing. Sizes 12", 14", 18" and 22" swing. Write for circular.

ROCKFORD LATHE & DRILL CO., Rockford, Ill.

WHOLESALE PRICES SHOW SLIGHT INCREASE

The monthly report of the department of labor at Ottawa, shows a slight upturn in wholesale prices. The index number of wholesale prices of all commodities stands at 226.1, as compared with 225 for the month of April; 247.3 for the month of May, 1921; 356.6 for May, 1920; and 136.3 for May, 1914. Iron and steel have moved from 182.5 for April to 184.2 for May. Other metals are practically stationary at 140.6, compared with 140.2.

Textiles show a slight advance from 227.9 to 228.6. The coal strike has caused a jump in coal prices, as indicated by the index number of fuel, which stands at 270.7, as against 244. Fuel and lighting together have advanced from 243.2 to 258.1. A pause in the downward trend in the costs of building materials is indicated by the fact that the index number for all commodities comprising this group now stands at 254.8 compared with 253.4. Lumber and miscellaneous materials have stood firm, and higher prices for paints, oils and glass are mainly accountable for the increase in the index number for the month.

Quebec.—The barge C. C. Donahuge, loaded 200 tons of newsprint paper a few days ago, and a second barge loaded a similar quantity directly after. These loads were shipped by the all-water route to New York. Some two years ago water shipments of newsprint were made to New York owing to freight congestion existing at that time, but the reason for resumption of barge trade on newsprint at this time is high freight rates. It is stated that European pulp and papers are arriving at New York at freight rates of from $3.00 to $4.50 gross ton, whereas the rail rate from Canadian mills averages $8.50 per gross ton. To offset this great difference, many Canadian industries are endeavoring to ship by water, and hope they will be able to meet the foreign competition.

The J. A. M. Taylor Tool Co., 77 Adelaide St. W. Toronto, have taken over two important lines, viz, Walker twist drills, and Greenfield taps and dies. Both mentioned companies will place a complete stock in the Toronto office, and Mr. Taylor will act as manager of Toronto and district sales. In other words, his office will act as a distributing point. All business closed will be invoiced from the head offices of his principals, the Walker Twist Drill Co., Wakerville, Ont., and the Greenfield Tap and Die Corporation, Galt, Ont., respectively, Mr. Taylor acting only as distributor for these lines. In addition to handling this work, he will continue to carry and sell his other lines, including files, hack saw blades, grinding wheels, etc. In these latter mentioned articles he will do his own billing.

The Toronto sales office of the John Morrow Screw and Nut Co., Ingersoll, is located at 172 John St.

W. H. Crowhurst has joined the sales force of the Kayser, Ellison and Co., Montreal, and will be located in the Montreal district. He was previously with Thomas Firth and Co., serving for 13 years, and for the past four years Quebec traveller for H. A. Drury and Company.

The Canada Metal Co., Toronto, have taken over the entire washer plant of the Union Iron and Metal Co., Toronto. This equipment is very complete, and over 400 different sizes of washers will be manufactured. The washer plant has been moved to the Graham Nail Works of the Canada Metal Co., this shop being large, well lighted, and convenient to the railway siding. It may take a little time before maximum production is reached, but once things getting running smoothly, they will be well able to cope with any demands. They intend to make this a jobbers and large manufacturers proposition, and with their own selling organization, expect to develop the industry to a large extent before very long. So far, they have had very favorable comments on the washers finished under their supervision.

SELL BRITISH ROAD ROLLERS IN CANADA

H. M. Trade Commissioner at Winnipeg reports that a United Kingdom manufacturer of road rollers has been successful in securing, in competition with foreign firms, a contract for two water ballast motor road rollers for delivery in British Columbia for the Canadian National Parks.

The United Kingdom firm in question is represented in Western Canada by a resident agent in Winnipeg, and the Trade Commissioner is of the opinion that its success is to be attributed in no small measure to this fact. Calls for tenders for supplies required by the Federal and Provincial Government Departments are made locally and often at short notice, and United Kingdom firms who are without responsible resident agents in Canada have very little chance of success in securing contracts, according to the report.

MILL RUNNING TO CAPACITY

Montreal.—Reports from Price Bros. and Co. mills indicate that they are running with a production of nearly 300 tons of newsprint a day. For all of this a market is assured. This condition, it is believed, will continue for the balance of present year. In addition there is some improvenment noted in lumber business, and within the last week or so the first shipment from the province for export to England took place, and it is expected that this will be followed by other shipments. During the past winter the company cut about 25 per cent. of its normal quantity of pulpwood and will go into the woods this winter probably for a normal supply.

BELIEVES WORST IS OVER, BRITAIN WILL SOON RECOVER

WE ANNOUNCED last week that J. G. Stirk of J. Stirk & Sons, Halifax, England, would be visiting Toronto within a few days. Less than 50 hours after his arrival in Canada we had the privilege of conversing with him upon conditions in England and other matters of interest to our readers.

Speaking about the industrial situation over there, he said: "I thoroughly believe the worst is over. Conditions are much better, and it looks as if the engineering strike is close to settlement. At least that is my opinion. The road ahead may be rather uphill, but I feel sure we will make the grade without difficulty."

Commenting upon the past war and if it had made any radical changes in the design of machine tools in England, Mr. Stirk said that it had not, although it had most assuredly taught them a lesson in simplification. To illustrate this point he told us the following story:

"Our firm, for example, handled about 20 different styles of machine tools before the war. Each of these styles had numerous sizes, so that the assortment was quite varied. Many of the types carried were only used occasionally, in fact some lines would only be called for about twice a year. The money tied up in patterns and other equipment was enormous and still we felt we had to carry them all.

"Then came the war and the need of machines in a hurry. Would you believe it, that for a certain length of time we made only one size of planer, a 5 ft. by 5 ft. type and had one order alone for 110 of these machines? These tools weighed roughly 25 tons each and we were turning them out at the rate of twelve per month."

When Mr. Stirk starts to talk about planers, you have him riding his hobby horse. He knows this style of tool from the ground up and is going to give us the benefit of some of his experiences in an early issue. Readers can look forward to this with keen interest.

Discussing the finish on British machine tools, Mr. Stirk said that British builders were paying more and more attention to the exterior appearance, without lowering the quality of the workmanship on hidden parts. He claimed that in the near future we would see a vast improvement in this respect. "So far we have built machines to do the work irrespective of the exterior appearance," he remarked, "but from now on, we are keeping in mind both quality and appearance."

Speaking about the absorption of discharged army and navy men, Mr. Stirk admitted the unemployment situation was rather bad, although not so acute as it was a few months ago. "As I said before," he concluded, "I believe we are safely over the worst and from now on, a gradual and steady improvement will take place."

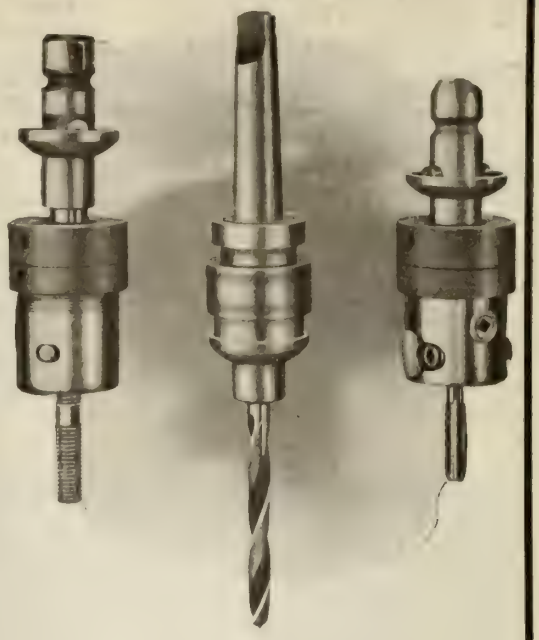
Tooling Up Your Engine Lathe for Turret Work

Jarvis Tappers and **Quick Change Chucks** and **Collets** are absolute necessities in to-day's production scheme.

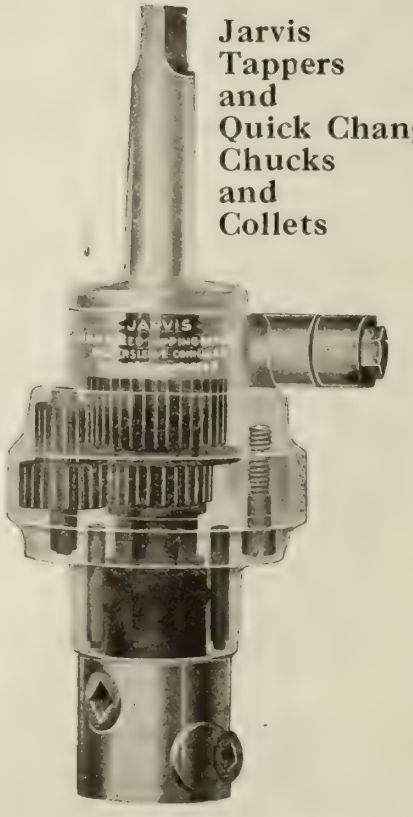
They are developed to a high degree of perfection and the **Geometric Tool Company** recommends and furnishes them as a fitting adjunct to their line of threading tools.

Jarvis Collets convert an engine lathe into a turret lathe by simply using one of ,the **Jarvis Quick Change Chucks,** which allows the use of any number of different tools.

The Jarvis High Speed Tapping Device is superior to any other.



It has a ball drive and ball reverse, making easiest action, with no clinching or binding. Reverse motion faster than the drive.



Specially designed Chucks make special taps unnecessary.

Jarvis Quick Change Chucks and Collets consist of a chuck or locking member and a sufficient assortment of collets for any job.

Where one hole is drilled, reamed, counterbored, tapped and a stud set, or any two of these operations are done with one spindle, the Jarvis Quick Change Chucks pay for themselves in a very short time. Changes are made without stopping the Drilling Machine or Lathe.

There is no burring from constant use to interfere with the easy entrance or operation of the Collet. If your product requires drilling, counterboring, tapping and stud setting, you need to know about the Jarvis. The Booklet tells the complete story.

C.P.R. LEADS WAY IN RE-ESTABLISHING GERMAN TRADE

"We have frequently expressed the opinion that no matter what sentiment we as Canadians might individually hold regarding the Germans, trade relations would be gradually resumed," says "Financial Post" in a recent article. They continue:—

"We have stated that sentiment would not hold out against economic forces, that to try to prevent an economic readjustment would do us as much or more harm as our late enemies. We have been soundly condemned by trigger-brained patriots who can not vision a year or so ahead.

"Last week it was announced from London that the Empress of France of the Canadian Pacific Lines had arrived at Hamburg with a cargo of Canadian products. This was the first trip in the new Germano-Canadian service. And the Empress of France was MADE IN GERMANY.

"In connection with this new service between Canada and Germany, Sir George McLaren Brown, British representative of the C.P.R., declares that 'Germany, which is now exporting a considerable quantity of goods to Canada will in the not far distant future take large quantities of Canadian raw materials and food stuffs. German supplies will have to be replenished soon and when exchange improves I hope that Germany will buy largely of Canadian grain and material products.'

"As a matter of fact the exports from Canada to Germany for the last fiscal year—ending with March—amounted to $8,215,337 as compared with $610,528 in the previous year, nothing in the war years and $4,004,019 in the year ending March 1914. In previous years the figures of German purchasers in Canada were:—1911—2,028,649; 1912—3,577,847; 1913—3,049,105.

"Thus we see that in dollars our exports to Germany are almost double what they were before the war. The value of the dollar is of course an important factor but still there can be no doubt that Germany is going to buy heavily of Canadian products. And who is going to suggest that we refuse to sell?

"This development would seem to be all the more favorable in relation to the all important balance of trade when it is stated that for the same fiscal period imports "from Germany" amounted to only about $1,500,000 as compared with nearly $15,000,000 in the year of the war. It must not be supposed, however, that these figures indicate all the German goods coming into Canada. When restrictive legislation went into effect German exporters immediately established connections with agents in Holland, Switzerland, England and the United States and made their consignments as exchange favored. We are to-day probably not only buying much more from Germany than the import figures indicate but much more than we are selling. It is for this reason that Canadian capital and Canadian labor look to the government to prevent the "dumping" into Canada of German products. We must expect to buy in Germany in order to sell but manufacturers and workers in this country should be protected from the competition of underpaid labor and debased currency."

LARGE BUCKET DREDGE BUILT BY CAN. VICKERS

The Canadian Vickers Co., of Montreal, has just completed the construction of the bucket ladder dredge No. 16, this being a sister ship to the dredge "Corozal," built by Messrs. Wm. Simons & Co. of Renfrew, Scotland. The No. 16 is one of the largest dredges of its kind in the world, being 292 feet in length, 48 feet moulded breadth and 20 feet 6 inches deep, fitted with two sets of buckets, one set with capacity per bucket of 54 cu. ft. and the other 30, cu. ft. per bucket. The vessel is of the twin screw type, driven by 1400 h. p. reciprocating engines. Two Scotch boilers are installed.

The vessel is electrically lighted. The upper deck is fitted with a 5-ton steam crane to assist in handling the buckets, and the bow and stern winches are ample for the handling of the fore and aft moorings, breast moorings and ship's anchors. The dredge has a capacity of 1500 tons of soil per hour, either into scows or hopper barges alongside, or into her own hoppers, and she is capable of dredging her own way through soil at a depth of 57 feet. It is expected that the dredge will be used in the ship canal below Quebec and be in commission before the end of June.

AGREEMENT REACHED

In return for a nominal royalty of 25 cents per long ton on all iron ore mined, the British Empire Steel Corporation has undertaken to construct in Newfoundland before 1928 a plant capable of producing 100,000 tons of iron or pig iron annually, according to an agreement between the corporation and the Newfoundland Government, made public here. The corporation further undertakes to erect coke ovens and to expend $3.000 000 in Newfoundland before 1926. All materials used in construction of these plants are to be admitted to the island duty free. The companies—Dominion and Scotia—are also granted certain rights as to tax exemptions and waterpower grants. The 25 cent royalty is to continue in force until December 1940. However, should the companies fail to carry out the construction program agreed upon, or should they fail to expend $3,000,000 in Newfoundland before 1926, an export tax of $1 per ton will be imposed by the Newfoundland Government upon all ore mined and shipped to any part of the world except Nova Scotia.

THERMOMETER FOR HOT ROLLERS

In paper-making and other machines heated rollers are used and it is a matter of great importance to keep the temperature of these rollers at the right degree. Hitherto it has not been easy to make accurate measurement of the temperature of the roller, but the difficulty has been overcome by a special type of thermometer devised by a British firm. The thermometer itself is of the ordinary mercury-in-glass type, but it is carried inside a steel sheath attached to an aluminum frame fitted with three wheels. Behind the bulb is a gilded reflector which reflects on to it the heat given off by the roller or drum, and behind this gilded reflector is a nickel plated reflector which prevents heat radiated by outside bodies from touching the bulb.

A REMARKABLE SAW

In the wood-working trades it has been customary to make joints by means of mortice and tenon. Joints made in this way require some skill on the part of the operator; and the exercise of skill involves some expenditure of time. There is among both professional and amateur wood-workers a demand for an effective joint which can be made more simply and without the same degree of skill. This demand is met by the use of a joint in which one or more circular discs of three-ply wood are embedded in semi-circular recesses cut in the pieces to be connected. The making of this joint involves the cutting of an exact half-circle recess in each of the pieces to be jointed. The ordinary saw cannot cut a recess of this kind, and consequently a British inventor has been induced to devise a special type of saw in which the operation can be quickly and accurately performed. A full half-circular slot, 3 in. in diameter, can be cut by this saw in ordinary wood in just over a minute. The machine is portable and can be put to work in practically any position.

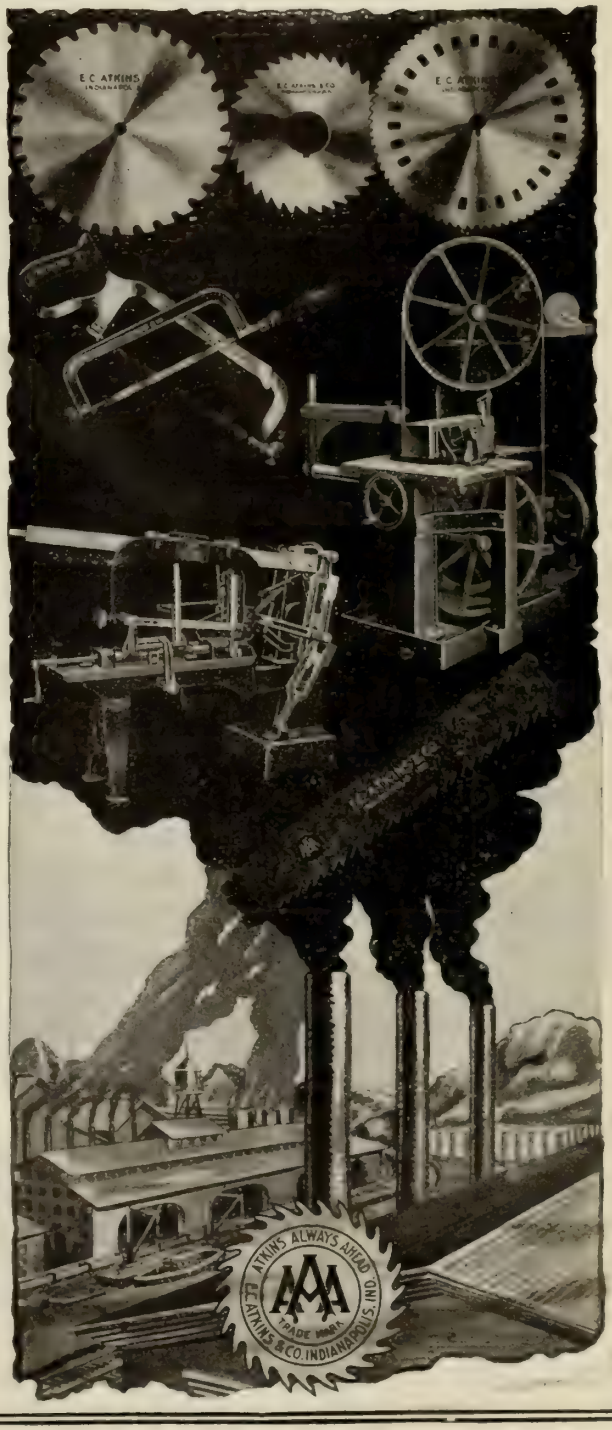
BUNDLING SCRAP

The disposal of old tins, kettles, old wire, sheet iron clippings, and other kinds of scrap metals is very much simplified if the material can be compressed into small bulk. In order to carry out this operation in the simplest possible way a British firm has devised a hydraulic press which can be operated entirely by unskilled labour and, if power is not available, by means of a hand pump. The press consists of a rectangular cast iron box with a hydraulic ram beneath it. The whole apparatus is let into the ground so as to bring the top of the box to a height convenient for throwing in the material. When the box is filled, the lid is swung over and pressure turned on. As soon as the maximum pressure is reached the operator releases the valve, swings off the cover, and the ram ejects the bale from the press.

ATKINS METAL CUTTING SAWS

Business Looking Up?

Building contracts are increasing, metal stocks are being depleted; factories are resuming; metal saws and machines must be ordered.



ARE YOU READY?

Put your plant in shape for a long run of good business. Write to the nearest point below for a catalog which will tell you why.

"Joy Shots" That Lead to Hell

By JUDGE EMILY F. MURPHY (*Janey Canuck*)

THIS IS the first of two articles in which Judge Murphy describes the menace that exists in Canada to-day in regard to the illegal traffic in narcotics. It gives actual facts from many Canadian cities and shows how the hypodermic needle is an even greater evil to combat than the opium pipe. The second of these articles will likely be in the July 15th issue.

Is Bootlegging a Passing Phase?

How common is bootlegging in Canada today? How do the members of the bootlegging profession carry on their business and what is their relationship to the officers of the law? These are two of the questions which are answered by A. Innes MacKenzie in a very colorful article describing the adventures, the fortunes and humorous rencontres of Canadian bootleggers from the Atlantic to the Pacific. Mr. MacKenzie writes whereof he knows, as he has spent several months studying this question and even associatting with many of the bootleggers themselves, in the interests of the readers of MACLEAN'S MAGAZINE.

Is the Canadian Flapper a Menace?

This is a question raised by Mrs. Gertrude S. Pringle in a startling article dealing with conditions as they too frequently exist in some Canadian centres. Extraordinary conditions are described by Mrs. Pringle, who is a thorough and conservative investigator. It is only too true, evidence regretfully shows, that some Canadian flappers are very much akin to their American sister who "parks her corsets and indulges in petting parties."

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

McKINNON BUILDING TEL. MAIN 7815 TORONTO

Be the first to take care of this new business in your territory

It is practically impossible nowadays to get away from the sound of an auto horn; the motor vehicle is found wherever a trail exists.

Motor car owners are not going to discard their cars as soon as something goes wrong, they will run into the nearest garage or repair shop. This often means a complete overhauling with the owner insisting that the cylinders be reground—it is a fact that motor car owners more than ever realize the advantage of a reground cylinder (not rebored).

Do your realize the volume of regrinding business that is bound your way and do you realize that it is the first man in the field who will get the cream of the business? Last summer proved a busy season for regrinding establishments (more especially for the small repair shop) and demands this summer will necessarily be greater. Why not take care of this business?

The Heald Style No. 65, which has been the choice of manufacturers owing to its massiveness and variable speeds and feeds, is now being adopted by regrinding shops—84% of the pleasure car manufacturers grind their cylinder bores and use a Heald exclusively.

The Heald Style No. 55 is a modified machine of wide range that fits mighty well in the small shop. It will handle the cylinders of any automobile and its price is quite easy. Send for Heald literature or a representative, you will learn more of the possibilities of proper regrinding equipment.

If conditions do not warrant your putting in equipment, get in close touch with some Heald regrinding shop and send him your blocks. The commission, without any effort on your part, will be "velvet," to say nothing about having a satisfied customer.

You will find the Heald a trade builder in every sense of the word as it means satisfaction to the owner and reputation to the repair shop. Get in touch with us today.

H.W. PETRIE LIMITED TORONTO

Machinery and Supplies

We can not only supply you with Heald Machines but every kind of machine tool you may require in your shop. Remember, Petrie is "Canada's Dependable Machinery and Supply House."

H.W. PETRIE

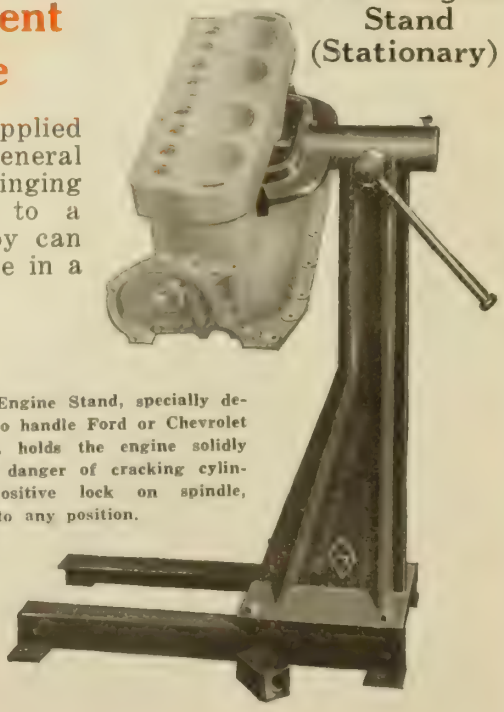
Jardine Garage Equipment

MADE IN CANADA

There's Money in Service—



Providing the service you give is up-to-date and really worth while. Jardine Garage Equipment is designed for speed, convenience and efficiency. Behind it is the definite Jardine Guarantee—behind that guarantee is the prestige of a concern of over fifty years' standing.

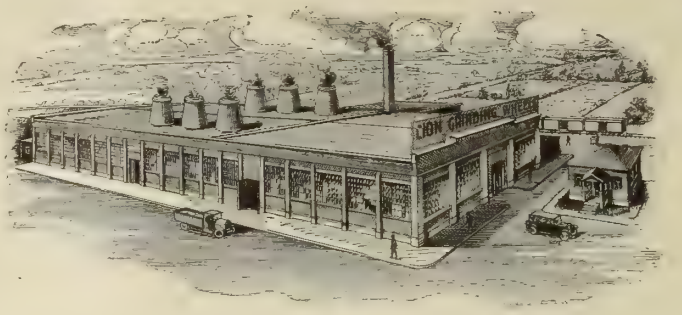
Jardine Equipment is Dependable

The Jardine Tire Changer (Patent applied for) is mechanically perfect, the general design and the compensating swinging jaws and rollers reduce friction to a minimum. A fourteen year old boy can change the most stubborn tire in a few minutes. Price $55.

Ford Engine Stand (Stationary)

FORD Engine Stand, specially designed to handle Ford or Chevrolet Engines, holds the engine solidly without danger of cracking cylinders, positive lock on spindle, swings to any position.

Tire Changer—For all Styles of Demountable Rims for Passenger Cars



Other Jardine Equipment includes Floor Cranes; Combination Floor and Wrecking Cranes; Garage Presses, absolutely guaranteed to 25 tons; Taps and Dies; Grinders; Blowers; Forges, and Drilling Machines. Write for catalogue G-22.

Agents for Quebec Province: J. R. BAXTER & CO., LIMITED., MONTREAL

Sold in eighteen different sets, in sizes to cut from ¼ in. to 1 in. thread, and furnished to conform to U.S., S.A.E., and Whitworth thread standards.

PRATT & WHITNEY
Screw Plate Sets

These reasonably-priced sets of standard P & W taps and dies, consist of our regular product made up in various combinations to meet the requirements of the small shop, garage, service station and general tool-room.
They are unequalled for fast, accurate threading of all metals and will be found invaluable whether used occasionally or for everyday work.

The taps and dies that go into P & W Screw Plate Sets are of a high quality unusual in such general purpose outfits. The taps are all made with the famous "con-eccentric" land—an exclusive Pratt & Whitney feature—that permits their resharpening on the face of the cutting edge without change in size.

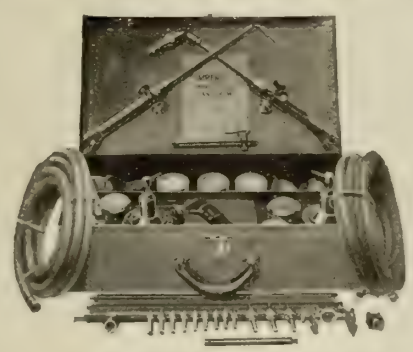
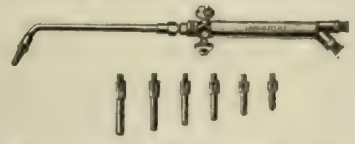
The Imperial Acetylene Generator Saves 2 to 4 Cents per Foot of Gas



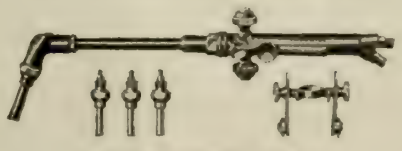
Automatic Acetylene Generator
Sizes: 15, 25, 50, 100, 200 and 300 lb.

All trouble, worry and expense of using acetylene gas in cylinders is forever done away with in the shops where Imperial Acetylene Generators are at work.

They are automatic—fool proof. When you want acetylene, it provides it, just as fast as you want it, and no faster. Turn on your torch, and the gas begins to flow. Shut off your torch, and generation stops.



That means you never run out of gas in the middle of an important job. It does away with the bother and expense of handling and hauling cylinders. The Imperial Generator is easily mounted on a truck to make it quickly transportable about the shop. In a short time, it pays for itself, for it generates acetylene at an actual saving of 2 to 4 cents a foot. **And it is not expensive.** Made in four sizes.



No. 5 Welding and Cutting Outfit
In Steel Carrying Case

Type B—Standard Welding Torch

Type A—Heavy Duty Welding Torch

Type EE—Cutting Torch

New Copper Tips for Imperial Welding Torches

We announce a great improvement—big news for every welder. Hereafter all Imperial Welding Torches are equipped with our new Imperial C. Welding Tips, which have been very carefully designed. Each is correctly shaped to carry the maximum amount of heat without loss by radiation. They are made of solid hard drawn copper rod, which is the highest heat-resisting tip material known, and are machined with ½-in No. 20 thread which gives greater strength at that point, and provides inside capacity for the taper bore. This taper bore construction increases the gas velocity, thus producing maximum heat and preventing back fires. Twelve different sizes—sold apart from torches when desired.

New Catalogue No. 165

Keep abreast of the progress in Oxy-acetylene welding equipment. Send for our new catalogue No. 165 on all Imperial Welding, Cutting, Carbon and Lead Burning Equipment and Supplies

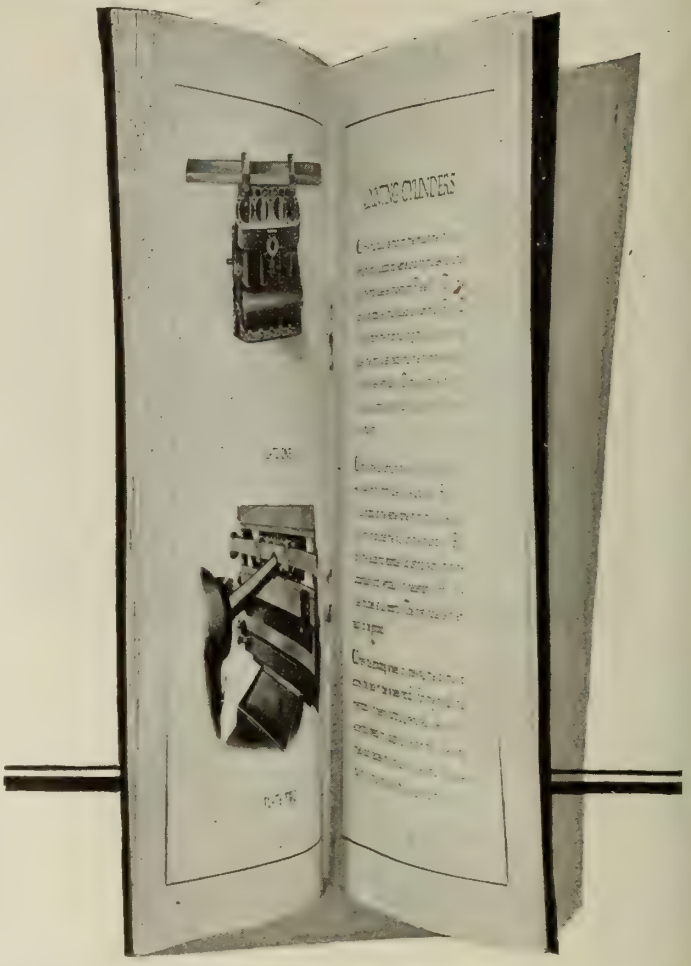
Do Your Share To Prevent Fires

Every man should do his full share to prevent fires and to reduce Canada's fire loss, amounting to millions of dollars annually.

Almetl Fire Doors and Shutters will give your plant the greatest protection against the spreading of fire.

The **Almetl** is built of corrugated steel interlined with asbestos and will withstand the most intense fire without twisting or buckling.

Reed's Fire-Tite oily waste cans should be in every factory, mill, power plant and garage, wherever waste is used. Built of steel, with light stork legs and self-closing lid, they are positive against spontaneous combustion fires from oily waste.



Made in three sizes.

Almetl Fire-Doors and Fire-tite oily waste cans bear the Underwriters' Label.

Write for particulars.

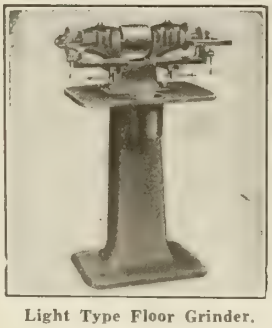
FORD-SMITH

Dies for Automobile Parts



The die shown here is a male automobile die and is used for blanking automobile fenders. It is one of the many dies made by us for the automobile manufacturers of Canada.

We Make Any Kind of Dies You Need

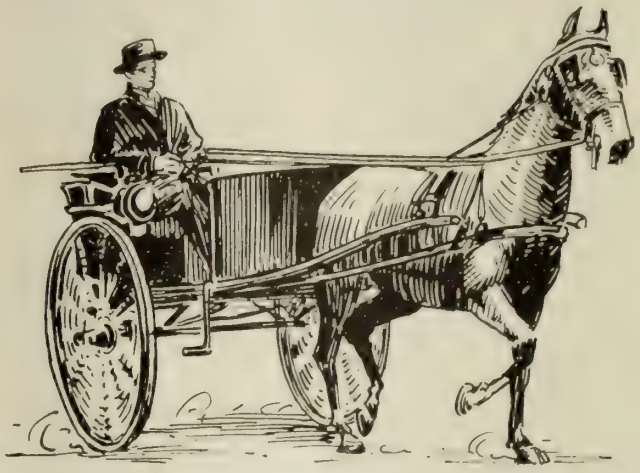
Dies for automobile parts represent only a few of the designs we make. We have the equipment and staff for designing and manufacturing any kind of die you require, and our designers are at all times at your service to instruct and advise.

GRINDERS
to Meet All Requirements

Light Type Floor Grinder.

From the Ford-Smith line of Grinders you may select the machine best suited to your class of grinding—General purpose grinders, disc grinders; all types, floor and bench, belt and motor driven. Polishers of all kinds.

30" Double End Grinder.



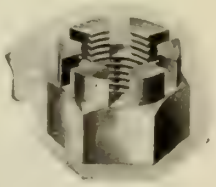
MALLORY TIMER FOR FORD CARS—It is the greatest ignition device ever invented for FORD owners. It is different from the ordinary timer, as the vibrating points are screwed down. We manufacture the MALLORY. Write for details.

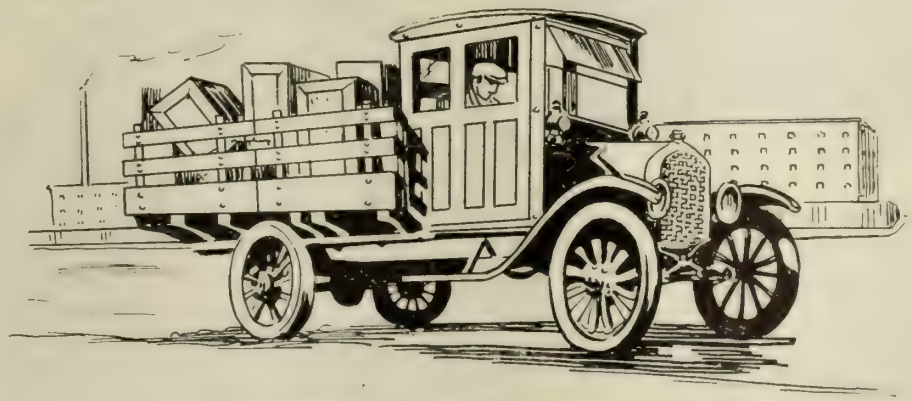
THE FORD-SMITH MACHINE CO., Limited

Hamilton, Ontario, Canada

Built in a Logical Way

RECOGNIZING that "there is always somewhere a weakest spot," the story goes that the deacon, in the time of George II built him a "shay" that had no weakest spot. After one hundred years' service it had not broken down, but just simply wore out. There was a maximum service in every part, "Step and prop iron, bolt and screw, spring, tire, axle and linchpin too, steel of the finest, bright and blue —she was a wonder and nothing less."





Galt Machine Screws

are made with the same care, skill and accuracy

Industry is trying to eliminate the weakest spot. In the building of chaises 100 years ago, so it is in the building of the modern motor car and truck. The best results demand products that are accurate, reliable, dependable. We adopt the highest standards, the utmost care in working out these essentials of satisfactory service.

SEND US YOUR BLUEPRINTS FOR ESTIMATES

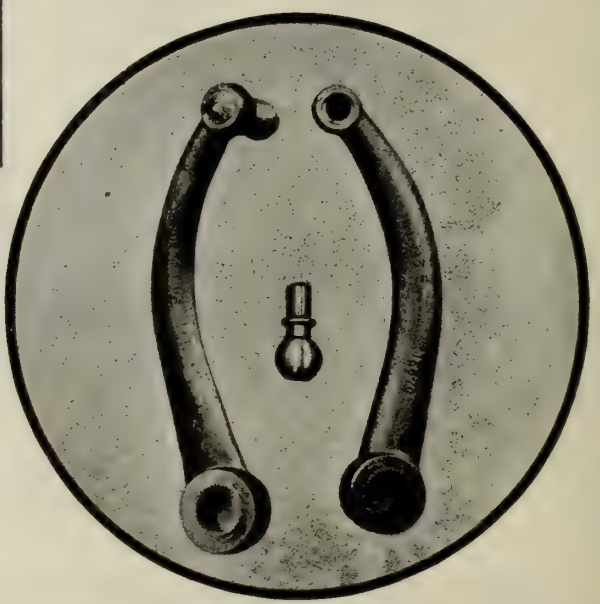
THE PRINCIPLE IS RIGHT

THE HAMMER WITH THE HUMAN STROKE



A No. 6-B HIGH SPEED RIVETING HAMMER

(PATENTED)

Gives remarkable Production on the Famous "Jacox" Steering Gear, where Dependable Riveting is Absolutely Essential.

The latest product of the High Speed Hammer Co., Inc., the No. 6-B Hammer, weighing a ton and a half, has proved one of the most efficient production units in the works of the Saginaw (Mich.,) Products Co. It is in this plant, (a division of the General Motors Corporation), that the famous "Jacox" steering gear is made.

This No. 6-B High Speed Riveting Hammer is being used for riveting a nickel steel ball to a forged steel pitman arm. The ball has a 5/8 in. shank, and is pressed into the arm by an arbor press. About 1/8 in. stock is left to rivet, and the machine turns the head over to 3/4 in. diameter.

On a 5-hour test run the remarkable production of 2,200 was obtained.

The No. 6-B Hammer is specially designed for heavy cold riveting. Its capacity is full round heads on 5/8 in. to 3/4 in. stock; oval or flush heads 7/8 in. to 1 1/2 stock.

Send us samples of your work and let us demonstrate **our process** of **cold** riveting on **your** own product.

Note How Rivets of Different Heights Are Headed Without Changing the Dies

A very interesting point about this operation is the fact that rivets of different lengths are headed without changing the dies, and by stopping the machine only for the fraction of a second. This end is achieved by two anvils operated by a foot pedal. High-speed Riveting Hammers lend themselves very readily to such labor-saving devices, which is one of the many reasons for their entry into such varied industries. This work is riveting double struts for auto tops. Seven long and one short rivet are headed in each set. There are two assemblies per set, production being 250 sets—4,000 rivets—per nine-hour day.

Send parts or prints for riveting sample and production estimate.

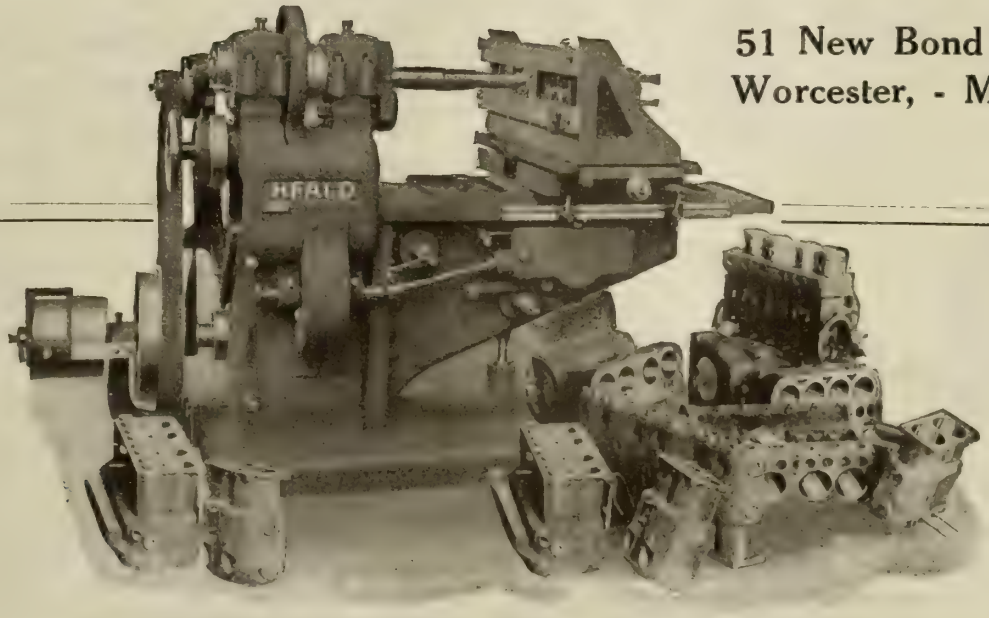
STYLE HEALD Nº65

For Centralized Repair Shops

If you are connected with automobile repair work in any manner such as a small machine shop, welding concern or even a regular garage, you are passing up an excellent opportunity if you do not look into the regrinding of automobile cylinders. Especially is this true if you are in the center of a large number of registered cars, not necessarily in the city but a strategic point in a medium sized town.

It is a new proposition to both repairmen and motor owners but its results are fast becoming known to both and the latter are, in a large percentage of cases, insisting on reground cylinders when overhauling to enable them to get a motor as good as new.

The commission usually allowed to garages is sufficient to make it a worth while proposition for them, especially when they are not in a position to put in the necessary equipment, and by obtaining work from all of these in your working center you will get unusually handsome returns on the investment. Once established you will create a market that now does not exist for there are many owners who do not know of the value of a reground block and still more who do know but neglect having it done owing to the inconvenience of sending the block away.



The Heald Style No. 55 was built especially for this class of work, simple, reasonably priced and with a range that will take care of any block that you may have whether it is from a pleasure car, truck, tractor, motorcycle or marine engine. Heald machines are used exclusively by every motor manufacturer that grinds his bores and motor owners who fully appreciate a reground job will insist on having it done on a Heald machine.

We would be glad to talk over the possibilities personally with you, giving you our frank opinion and furnish you with sufficient information to enable you to decide for yourself whether you can make a success of it or not.

Get in touch with us direct or through our branches or agents.

Old Man Johnson
And
His Sled Waste Oils

Are you paying $1,200 a year to old man Johnson? He is that unnecessary man who fetches and carries oils and varnishes from a wasteful storage house to the different points of use. Having him around means that you are wasting oils, for depreciation is fast when air reaches them.

And give old man Johnson a productive job. Install Bowser equipment. Stop this waste.

Barrels can then be immediately and completely emptied and returned for credits or sold. New purchases are checked on receipt by the Bowser gauge. Oils and varnishes stored indefinitely without evaporation or deterioration in quality. Minimum insurance rates are assured. Labor in handling is saved. There is no spillage or waste.

Write for Bulletin C-13 and let us quote actual examples of money saving installations of Bowser equipment for finishing oils and varnishes.

A New Tool

For a troublesome job

The "Davis"

Valve Reseating and Boring Tool

is the only tool on the market that can properly do this important job. One reason for its perfect work is the fact that a large, accurately ground bearing above the valve seat guides the cutters with a sureness impossible by any other method. In addition, the Davis tool is held to the cut by a perfect screw feed device, no digging in, no sliding over cut, no chatter, **every seat a perfect job.**

People are turning more and more to the shops that have the tools and equipment for doing their work **best.** You cannot afford to neglect any opportunity to keep pace, at least, with your competitor. And the Davis Valve Reseating and Boring Tool is just one of those things that often cinches a customer's future trade. Who is to get it, you—or the other man?

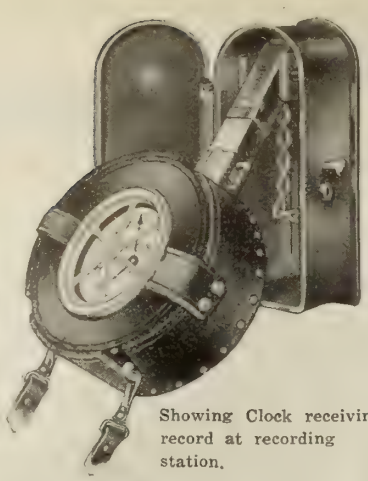
SKF

When the Cutting Tool "Bites"

What Happens at the Head Stock Bearings?

HIGH speed cutting tools, hardened cut gears and improved design of spindles and head stock give modern lathes ability to take heavier cuts and higher speeds as part of the day's duty.

The heavy shocks and strains which pass back from the cutting tool can be transmitted by **SKF** marked thrust bearings to the head stock and frame without wear, friction or heating in the bearings. Freedom of running and lack of friction eliminate the dragging, binding action of fibre or metal washers in ordinary thrust bearings and save energy which is utilized to furnish more power at the cut.



In fact **SKF** marked ball thrust bearings run for years with no appreciable wear and without necessity for any take up or adjustment. They increase the life of the lathe, decrease the power required and make the production of more accurate work possible.

The experience of our Engineering Department in applying ball bearings to machine tools is at your service. We will be glad to give estimates or advice without attaching any obligation on your part.

CANADIAN **SKF** COMPANY, LIMITED

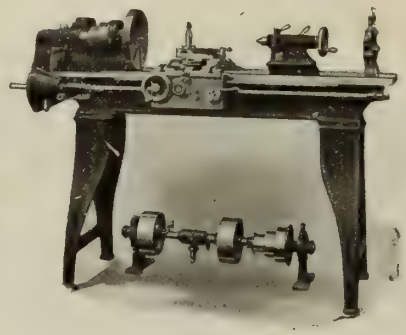
Watch Your Watchman!

Showing Clock receiving record at recording station.

WHEN you pile into your bed every night do you ever stop to realize that you are entrusting, absolutely, the source of your income to a low-salaried watchman **without proof that he is actually "on the job"?** True, you have your fire insurance, but that is merely indemnity for buildings and material destroyed. It pays you nothing for loss of production, organization and time.

The Hardinge Alert System is your Factor of Safety. It tells you, beyond argument, whether you are getting all the protection you pay for. If your watchman is "on the job," it tells you so—if he's a slacker, it tells you so. It cannot lie, the watchman makes the record himself. By his own hand he tells you whether or not he is faithful.



There's no wiring, no complicated installations to the Hardinge Alert; your workman can equip your plant in a couple of hours.

Let us send you a system for thirty days' trial.

CANADIAN MACHINERY
AND
MANUFACTURING NEWS

Vol. XXVII. No. 25 JUNE 22, 1922

From a Novelty to a World Wide Necessity

Down the railroad track came a galloping horseman; close on the heels of the horse followed a panting steel monster. A man guiding this contraption, from which belched forth volumes of black smoke, yelled for the horseman to get off the track, and, upon his command being obeyed, he opened a throttle, speeding up his locomotive to the then marvellous rate of 12 miles an hour. In this spectacular fashion, George Stephenson introduced to the world the rail method of transportation.

The development of railways since that date reads like a romance, and this romance has been repeated in recent years in another innovation which has shown a progress equally remarkable to that of the steam locomotive. Picture to yourself for a moment the first gasoline driven vehicle. Crude, clumsy, expensive to operate, and far from pleasing in appearance, it was looked upon as a useless new fad, yet before long its possibilities began to make themselves felt. At first the complicated mechanism was against it, and had it not been for the faith of its inventor, who knows what the future of the automobile might have been!

With a persistent belief, however, in the commercial value of this new idea those interested persevered, until at the present day, obstacles have been largely overcome, new pleasing lines developed, and efficient power plants installed on modern autos. Simplicity has been the keynote of success in the automotive industry, and this feature has been chiefly responsible for the present popularity of cars, both pleasure and commercial.

At the present time the world would feel lost without the automobile as a method of transportation. This system of travel has broadened every field of endeavor, has developed new markets, aided agricultural development and helped the farmer to reach his special markets. Other lines of business have been likewise benefited and the value of the automobile and truck to the world in general cannot be figured in dollars and cents.

A modification of the automobile engine has also proved itself invaluable for harvesting uses, and we now see on the modern farm, gasoline driven plows, harrows and other similar implements. All over the country we find motor trucks carrying commodities to and fro, quickly, without damage, and economically. They have proved themselves a decided asset to business and a speedy means of transportation.

In 1809 it cost 75 cents to move a bushel of salt from the mouth of the Niagara River to the head of the falls, a distance of 28 miles, and in 1824 it took 20 days, and cost $100 to move a ton of merchandise 224 miles. In comparison with the low running costs of 3 cents per mile for a motor truck fully loaded, one can readily see the phenomenal improvement which has occurred since that date.

Manufacturing methods of automobile construction have kept pace with improved design, this bringing the selling price of the product within the reach both of merchant and individual. In the following pages we show how several makes of cars are produced, but these stories are but sketches of a gigantic industry, an industry so large that it is impossible for the average individual to gain any adequate idea of its magnitude unless he visits several of the factories engaged in this work and sees for himself the number of men engaged and the vast capital which has been invested.

Canada may well be proud of its automotive industry for it has developed by leaps and bounds in the last decade and will still further develop as time goes on. He would be a rash man indeed, who would prophesy the type of car used ten years from now, for with designers straining every nerve for economy and simplicity, who knows what the future holds?

Gasoline may even be superseded by some cheaper and more efficient fuel, be it refined oil, a chemical combination, or other liquid. Time alone will tell what the improvement will be, but one thing is sure, the future car will be even further simplified than it is at present, and will be more economical in fuel consumption. All things point in that direction, and with the best brains of the automotive industry centred on these objectives, failure is well nigh impossible.

Producing *55,000* Cars and Trucks a Year

General view of the Ford plant at Ford, Ontario.

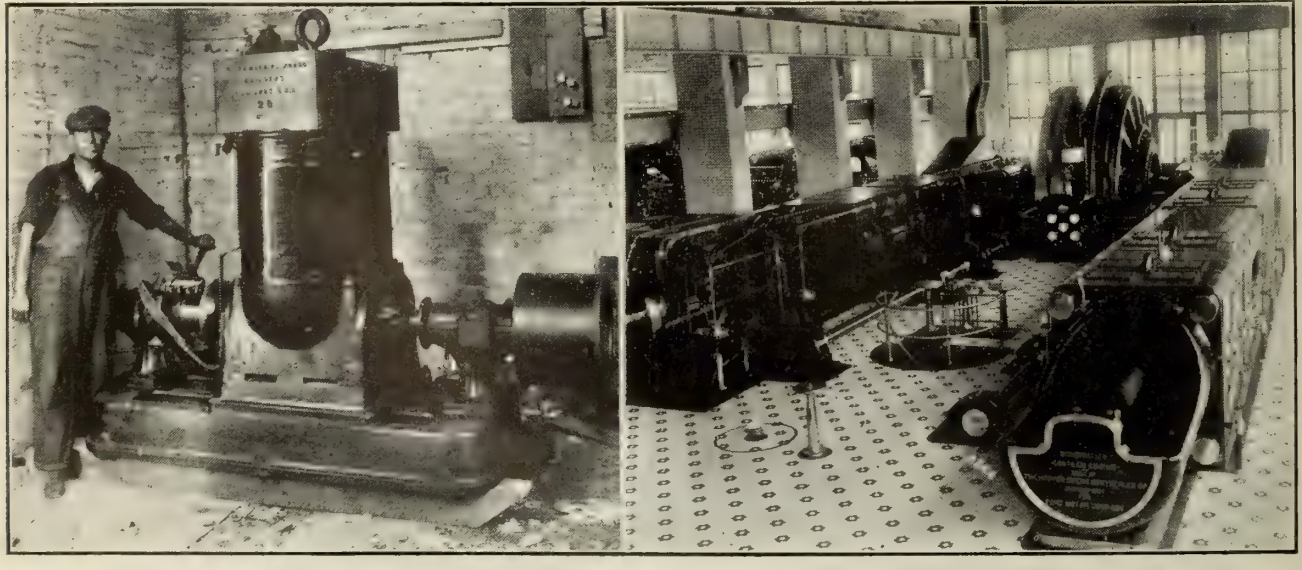
A HUGE enterprise turning out a carefully manufactured product. A well arranged plant with a splendid balanced organization. These thoughts, and many others of similar nature, came to our mind when we visited the plant of the Ford Motor Company of Canada, at Ford, Ontario.

Quietly, yet very efficiently, this organization is producing approximately 55,000 cars per year. This figure includes cars and trucks only, as tractors are not made in Canada at the present time. Just picture for a moment what this rate of production means, then read the following figures, which will be eye-openers to many we feel sure.

The plant itself is valued at $8,683,091—this including all departments, which although housed in different buildings, are all part of the Ford plant.

The total floor space occupied at plant is 605,000 sq. ft., and at the branches, 428,000 sq. ft. Over 3,100 employees are engaged in the factory and offices. The average daily payroll amounts to about $20,000, this including only the main factory and office. In addition to these items several other factories are employed on Ford work—thus adding of course to the figure given. Then there are 14,159 employed in the different branches, service stations, and dealers throughout the country.

During the fiscal year ending July 31st, 1921, the Ford Co. purchased from other Canadian firms $19,000,000 worth of products. This included bodies, tops etc. Approximately 40 firms received the benefit of this business, and in about 50 per cent. of these cases, the plants turning out parts for the Ford car, are wholly engaged on this work.



In fact, from statistics, we find that about 30 per cent. of the population of the Border cities, is directly dependent on the Ford Co. for their livelihood, and approximately 40 per cent. indirectly employed on work for the main plant. These figures show conclusively the importance of the automotive industry in this section of the country.

Going further into the matter we find that the railways get their share of the work created, for it has been figured out that practically 1,000 railroad employees are busy shipping and handling Ford Cars and parts every day of the year.

The progress made in the plant and its output, is remarkable. In 1910, the total valuation was only $73,921, against the present figure of over eight million, and the production in 1905 was only 117 cars, against over 55,000 at the present time. Only $47 is spent for imported material on each car made in Canada, all other parts being Canadian. In 1921, 46,500 cars and trucks were sold.

Would You Believe it?

When you see the next Ford car, think of the following figures which are facts culled from many others, and based on the amount of material used every year when making various parts of the car.

Showing the old power plant and a corner of the new. Note the combination gas-steam engine in right hand photograph. There are two of these engines, in addition to other power units.

On magnetic construction, some 718,000 lbs. of special steel are used, and 1,720 miles of wire. In making gasoline tanks 496,000 sq. ft. of galvanized metal is used, also 3,000,000 sq. ft. of sheet steel for car body construction. Over 1,500,000 ft. of steel rods is used to make radius rods, and other similar parts.

The tool equipment in the machine shop uses over 800 gallons of lubricating oils, and more than 7,500 gallons of cutting compound. To make 50,000 cars, over 25,000 tons of steel are required, and more than 3,000,000 sq. ft. of top material. Then there is the question of 200,000 wheels and tires, 150,000 lamps, headlights, etc., and more than 250,000 sq. ft. of plate glass. Over 7,000,000 ft. of copper tubing is used every year, but it is unnecessary to go further, for the figures given are ample proof of the magnitude of the plant and its demands.

The automobile industry, like many other industries, had first to pass through the skeptical period, and when the late Gordon M. McGregor first started his tiny plant, making Ford cars, many shook their heads and prophesied a horrible failure. The company was organized in 1904 with a capitalization of $125,000, and has increased rapidly between 1911 and the present time. It now has factory branches in nine Canadian cities, and has grown into the automobile factory with the greatest output in the British Empire.

A first the proposition was chiefly one of assembly of imported parts from Detroit, but after organizing in 1904, the new firm shipped its first car in Feb. 1905. The entire sales for this year amounted to only $110,000 and the only machinery for automobile finishing to start with was a solitary drill press, but now in the machine shop alone, there are over 1,700 machines in operation, these being valued at $2,186,000.

In the old days, when power was required to run the drill press, or elevator, a belt was attached to one of the rear wheels of a model "C" car, and away went the factory. Compare this with the present power house illustrated in this article. There is no need of following the growth step by step, but rather consider the present modern plant with its total of 600,000 sq. ft. floor space.

Fig. 1.—Showing how pistons are turned, grooved and faced.

Trip Through Factory

When we started on this trip we realized that unless we were prepared to devote an issue to a detailed story we had better stick to a brief description of the plant methods, for there was so much to see and talk about. Starting with the miscellaneous stock room, where many varied parts are stored in neat bins, and carefully carded and checked, we passed into the electrical department where the operations on magnetos, generators, and starters are performed.

Everything is carefully planned, even the benches, which are equipped with a slow moving belt carrying the work along by gradual stages. Jigs and fixtures are the rule, not the exception, and even when winding the copper tape into shape, a special arbor and winding machine is employed. When stripping the wires to obtain the bare ends, a knife, operated by foot treadle is used by the operators. They merely slip the end of the wire between a plier-like knife, press the foot, which brings down the knives, then a slight pull, and the end is stripped. Even when tightening the screws in the field coil of generator, a jig is used, which guarantees that the screw will be absolutely tight. This is very necessary, and pays the firm to arrange the operation in this way.

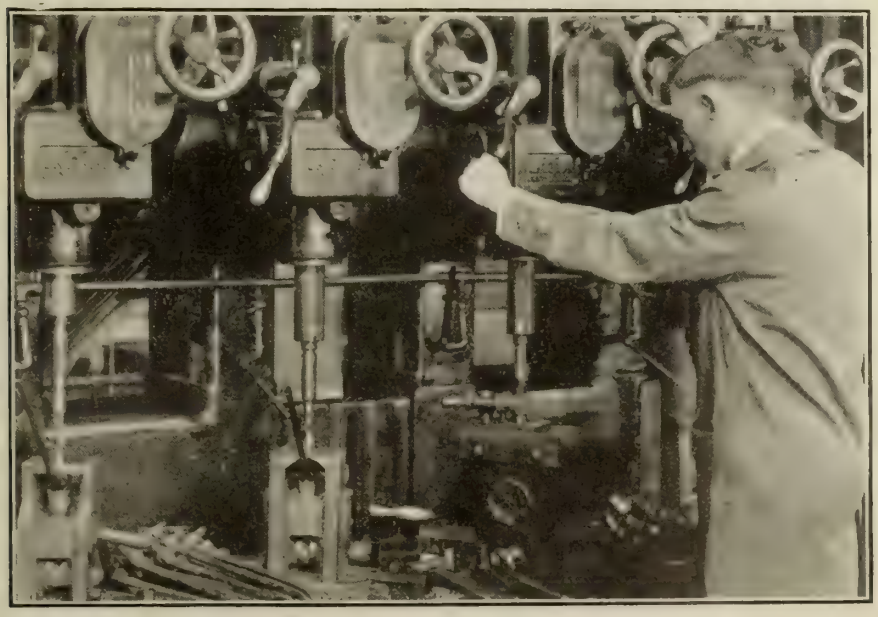


Fig. 2.—Drilling front fender iron and spring perch.

The coils are dipped and baked in the electrical department, but as this is a specialized operation we will not dwell at length on the process.

We next passed into the machine shop, which includes various departments, such as the press, automatic, cold bolt header, bolt threader, die castings, and electro plating departments. In the press section, we find all sizes of presses large and small, and the variety of work completed, ranges from small stampings to the heavy crank cases. One press weighs 52,000 pounds and has a pressure of 900 tons. The crank cases are drawn to shape on this huge press, and the parts after being drawn, are annealed in nearby furnaces between each draw.

The complete machine shop is 705 x 210 ft. and every machine used is made as automatic as possible. For example, on the bolt headers, the feed is automatic. In the bolt threaders, either hoppers or automatic gripping fingers are used, and this applies to both the rolled thread and die-cutting machines. When making the running

board, a special machine is used, and the flat strip of steel passes between rollers and dies, the necessary trade mark and embossed foot treads being completed at the one pass.

Everything in Sequence

The chief feature of Ford methods, is systematic production. As far as possible everything passes on, and keeps going, not turning back for minor operations. This meant careful arranging of equipment, and the present state of perfection was not reached overnight, but has taken years of patient study.

Take for example the operations on the cylinder. This includes milling and drilling. Every operation is a follow up of the other, and when the block reaches the end of the line, it is completed so far as machining is concerned. To start with, a huge milling machine finishes 15 blocks at one time, milling the top face and side lugs simultaneously. This is made possible by a special jig arrangement accommodating several blocks in position to machine the top, while other cutters are set at proper spacings in order to machine the side lugs.

In another special milling jig, attached to a continuous miller, 44 valves are held and machined. The stems of the valves are placed in holes equally spaced around the circular and as the valves move under the milling cutter, a roller holds down the valve while the bottom of stem is faced off to proper length.

On a drum type continuous milling machine, 8 axles are machined continuously on twelve faces. The fixture itself is extremely simple, merely holding the axle while the 8 faces at fork end of axle are finished, also the four faces at the spring pads.

An ordinary 20 in. drill press, fitted with a special milling attachment, is used to machine six bosses on the transmission cover, and this is arranged as follows. Six cutters are attached on special spindles the proper distances apart, and these get their power from one main spindle which is connected with the gearing of the machine itself. The cover simply slips in place, is fastened by a swinging clamp and all bosses are milled simultaneously.

The four holes at the crank end, of crank shaft, are drilled and reamed on a vertical circular jig which holds four shafts at one time. A multiple spindle drill press is used, and eight spindles are in operation, six being equipped with drills and two with reamers.

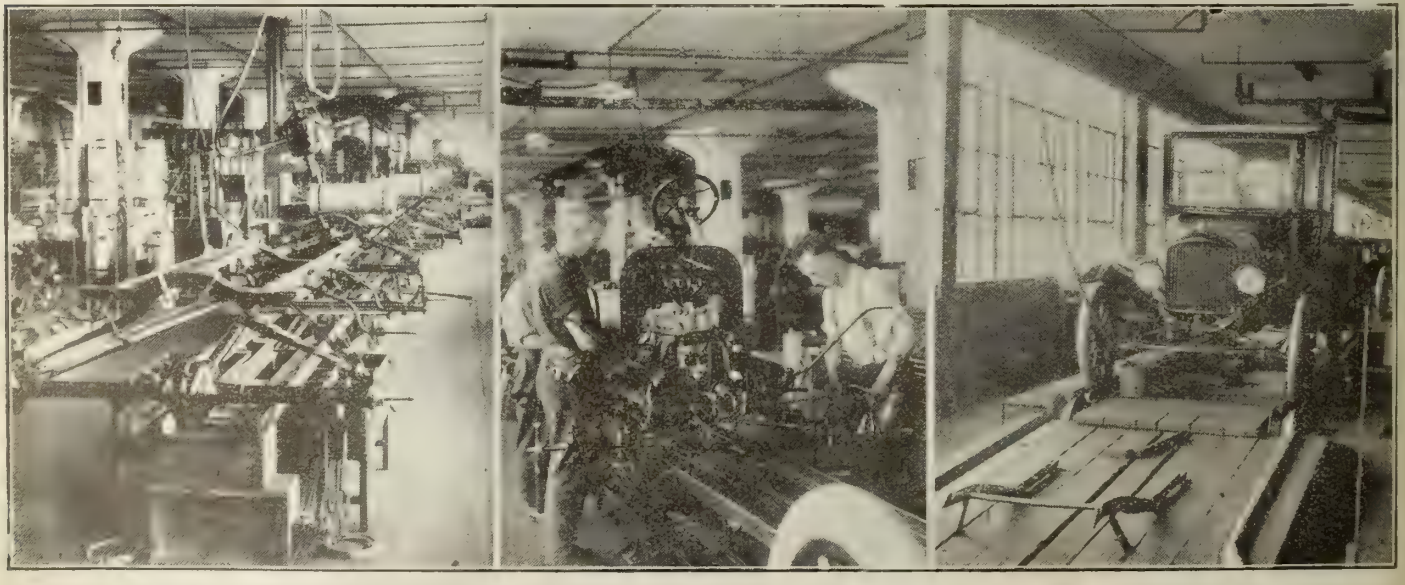
The method of polishing the cylinder bores after machining is worth mentioning. A special machine is equipped with spindles having a series of rollers at their ends. These are used as burnishers, and bring the bore to a good, high polish.

Another machine of interest is the one shown at Fig. 4. Here we see the turning and grooving of pistons, also the facing of top. On the table of machine are shown some castings partially and finally completed. The operation is somewhat similar to any vertical boring work and the only difference in this case is that every hinge is self-contained and specially tooled to suit this particular part.

Fig. 2 shows the drilling of front fender iron and spring perch. The two left hand spindles complete the one part, the other spindles completing the spring perch. This is a straight drilling proposition, but note the method of holding fender iron in position by means of the quick-acting clamp, or plunger, based on the cam principle.

Motor Assembly

On the second floor is the motor assembly, and again we find the value of careful planning. Everything is done in sequence, and each man has a specified task to perform. After the valve springs are put in place, the crank shaft is installed, and the main bearings tightened down. This being completed, the engine is run in a special burning-in stand for three-quarter of a minute, and is run dry. The bearings are now removed, inspected, and if scraping is necessary, the operator makes everything O. K.



The connecting rods, pistons with rings, etc., are next installed, and these are run in for a suitable length of time. From then on many things happen. The magnetos are tested, assembled, and then a timing test on the engine takes place. The operator keeps grinding off a portion from the ends of the valve stems until everything is timing properly.

The transmission is now placed on the engine, after which we come to the assembly of the magneto, starter gear and flywheel. These parts are also assembled to motor, brake band lining, crank case, universal ball cap and starter being added. At this point they come to the end of the slow-moving assembly chain, where they are picked up by the hook shown at Fig. 3, where they are swung over to the running-in stand, the transmission cover being put on at this point.

The Test

The complete motors are next placed on dynamometer test stands, and driven by a 20 h. p. electric motor. They get a 15-minute running test in oil, the speed being about 14 m. p. h. Later on the engine is run under its own power and put under the regular S. A. E. tests. Should anything occur which shows the engine is not working properly, it is promptly torn down, the defect remedied, and tested once more. This is done until the inspector puts his O K. on the finished motor.

On the third floor we have the front axle assembly and the method of testing is worthy of mention. A special jig fits over the completed axle. The radius rods operating the knuckles, are moved around as if the axle were in actual use, until every point registers properly. The operator then knows that if the axle were assembled in a car, it would guide the wheels in proper manner.

Reading from left to right, Figs. 5, 6 and 7, showing step in the assembly of chassis, tightening up of motor fittings, and the completed car just before the test run.

We now come to the assembly of rear axle, and without entering into the operations step by step, sufficient to say that all axles are tested before being assembled on to the motor. This test is shown at Fig. 4. As the axle reaches completion it is attached to motor shown, and run in until passed by the inspector. Should trouble arise, the whole thing is torn down the same as the motor, and the defect remedied. The test is very exacting, as the motor and rear axle are, after all, driving members of the car.

The different units being completed, we come to the final assembly. Again we will not attempt to touch on every operation, but will show by three photographic reproductions some of the stages through which the car passes. At Fig. 5 we see the chassis assembled to the front and rear axle, springs, running board, braces, etc.

From this point on the gasoline tank is added, the steering wheel and panel, motor and so on, each part being added as best suited to the completed car. Accessibility is one of the main considerations, and as the chassis passes down the slow-moving chain, it is wonderful to see the framework looking more and more like a completed car.

During these stages of assembly, hand power is supplemented with air and electric power as much as possible. When tightening bolts, the air speed wrenches are used, and except in such cases as Figure 6, hand-tightening is done away with.

To show how carefully every step is planned, here is what happens when the car has reached the stage where wheels and tires are required. On the floor above, the tires are placed on the wheels, inflated, then put into a chute leading to the final assembly floor. These reach the assembly line at the proper point, and all the workman has to do, is pick a wheel up, place it on the axle, and repeat the performance until the car is fully equipped with tired wheels.

At Fig 6 the men are making sure that the motor is properly fitted up, the placing on of wheels being the next operation. The bodies of the cars are placed in position by means of a monorail system, part of which can be noted at Fig. 7. This view shows the car just before the test is run. When it reaches here, there is gasoline placed in the tank, and the car is ready for a test run. Note in this picture, the two grooved wheels, and the flat iron cradle affair on the forward platform. This is used for starting purposes, when the engine is new and perhaps very stiff to turn over.

The car is moved until the rear tires rest on the grooved wheels and the front axle is locked in the cradle. A motor, not shown in photograph, starts the grooved wheels in motion, this of course operating the rear axle, thereby driving the engine through drive shaft transmission. As soon as it is warmed up, the car is taken out for a test drive by competent inspectors and until the man puts his O. K. tag on the car, it is not considered a completed article. The patience and perseverance displayed in this department is remarkable, but the slogan is "Make the car right at all costs."

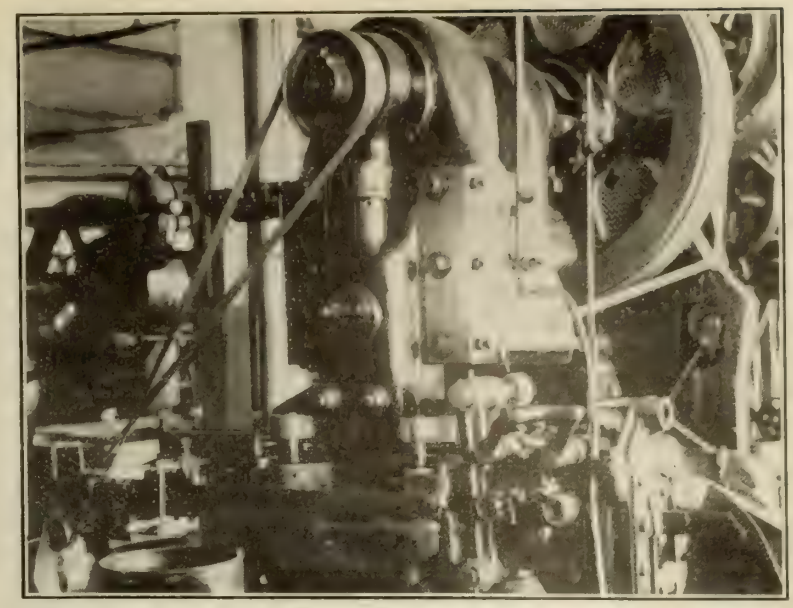


Fig. 8.—Stamping radiator fins automatically from a roll of brass sheeting.

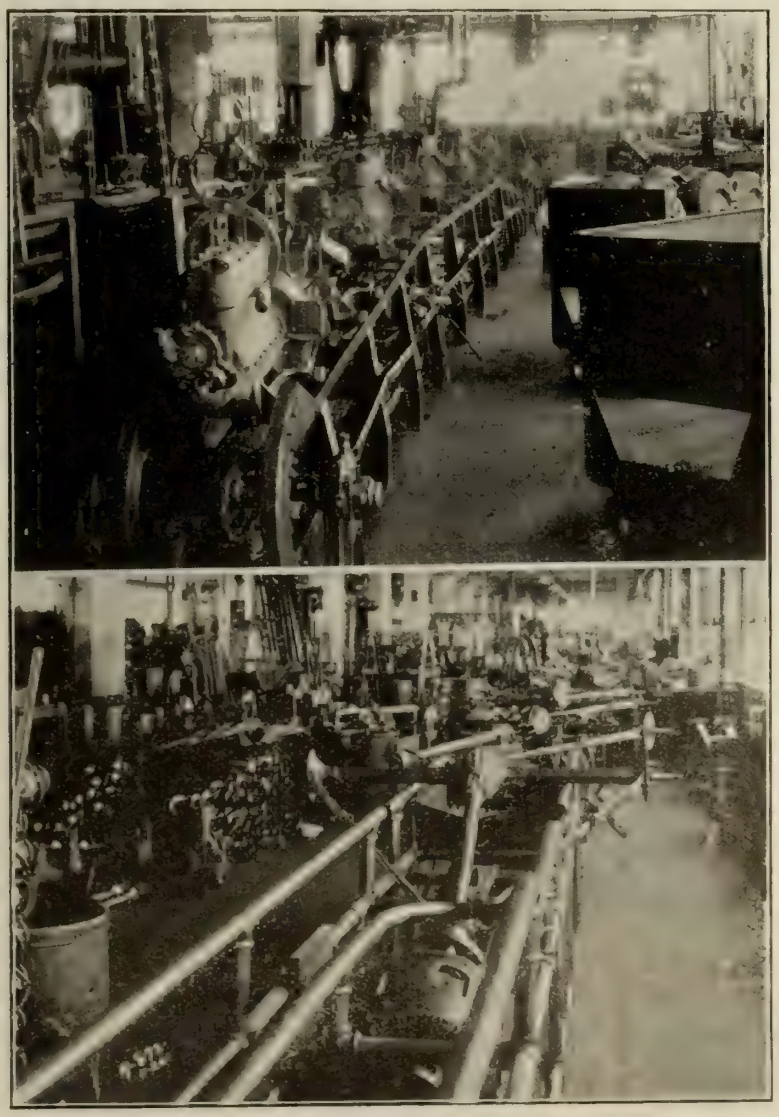

Fig. 3.—Upper view showing engine ready to be picked off assembly chair and swung over to running-in stand. Fig. 4.—Lower view showing step in assembly of rear axle.

Having followed the car through its assembly, we shall briefly dwell upon varied operations entering into the making of the parts. Take for example the radiator department. Here we see the radiator built up gradually, and Fig. 8 shows an interesting operation in this section. The radiator fins are stamped automatically on the press shown, and a roll of brass sheeting of the proper width is placed on a reel at one end of the press. An automatic feed and trip does the rest. In comes the stock, it is rolled over at the edge, the proper number of holes punched in the part, and as it leaves the press, it is sheared off into proper lengths, and drops down a chute into a container.

The method of assembly is interesting. Jigs are used, and into these fixtures are placed the fins we have just referred to. At another part of a circular table, (for the operation is arranged in this manner) a workman has a large number of tubes, which he simply pulls around in a jig until almost before you realize it, the tubes are all in place. They are next pressed out from this jig by means of air, into the fin jig and of course as the fins are encased in the fixture, the operation becomes merely one of routine. The present method however was only arrived at through painstaking experimenting. Other operations are sweating, soldering, etc.

The sheet metal department is a plant in itself, and owing to the extreme length of this article, we will simply pass the matter up by mentioning that only first-class equipment and dies are used. Here again we see that every operation is carefully planned in sequence, this making for good production.

Heat Treatment

A department which must not be overlooked is the heat treating section. Here all parts to be treated are placed in the furnace and according to the material and use to which the part is put, the chief furnace control man gives it the proper treatment. The method of control is splendid. In a room, above the furnaces, are several men, who although they seldom see the material going into the furnaces know exactly the moment it enters and issue orders when it must leave. The men attending the furnaces are not heat treaters in the actual sense of the term, but are ideal order attenders. They work through a series of lights, and these bulbs tell them what to do. Red, white, and green are the colors used, and here is how the system is operated:

A small card is issued by the foreman of heat-treating room to the control room stating that such and such a part is ready for heat treatment. The control operator then makes out a card stating the furnace into which the parts are to go, the time they must enter, and the maximum temperature to which the oven must be heated.

Suppose the parts have entered the furnace and the heat registers much too high on the control pyrometer, then the operator flashes a red lamp on the furnace attendant. Should the heat be only a little higher than necessary a red and a white lamp are lit. A green light tells the attendant that the heat is much too low, while a green and white signal means just a little too low.

When all three lights show at one time it indicates to the furnace man that he must load up. In this way, guess work is eliminated and the control board operator keeps a very close check on all parts passing through his hands.

For example, here is how one of the furnace check cards was made out while we were there. Gears were being heat treated and the batch consisted of 250. The date was clearly shown, and the time of entering the furnace, viz. 11.30 a. m. The time out, 2.15 p. m. was also registered, and the furnace number was twelve. It was stated on the card that the furnace used was air and gas, and that the maximum temperature was 1,560 F.

A check on the furnaces is made every 15 minutes, and in some cases, a soaking heat is given, after the furnace has been brought up to the proper temperature. For example, some of the gears for the back axle are heated to 1,560 F., then allowed to soak for several hours.

To know just where to stop in an article of this nature is difficult, for there are so many points of interest to discuss. There is the printing plant where all sorts of circulars, letter heads, and so on are produced, and there is the photographic department where moving pictures and still photographs are made and developed. At present they have eased off on the motion picture section, but ordinary photographs are being taken at all times.

Then they have the power house, which is illustrated in this article. Here they produce 26,000 k. w. hours per working day of 8¾ hours, with two engines, other engines are held in reserve for emergency use. The large engine has a rating of 5,000 h. p. and is of the special gas-steam type. There are four smaller engines totaling 3,000

Figs. 9 and 10 showing method of placing material in box cars, also system of receiving and distributing goods to other plants, etc.

h. p. There is layout, equipment and space for another 5,000 h. p. engine, which will be installed at some future time. A full gas producer plant is in operation, supplying gas for the engines, and other purposes.

Methods of Packing

To leave the subject without mention of their excellent packing methods would be unwise. Here again, every step has been carefully thought out, and every workman knows his duties exactly. He contributes his share to the packing of the car, and usually these men work in teams. The cases are made sufficiently strong to stand the railway journey, and as considerable export business is done, this precaution is very necessary.

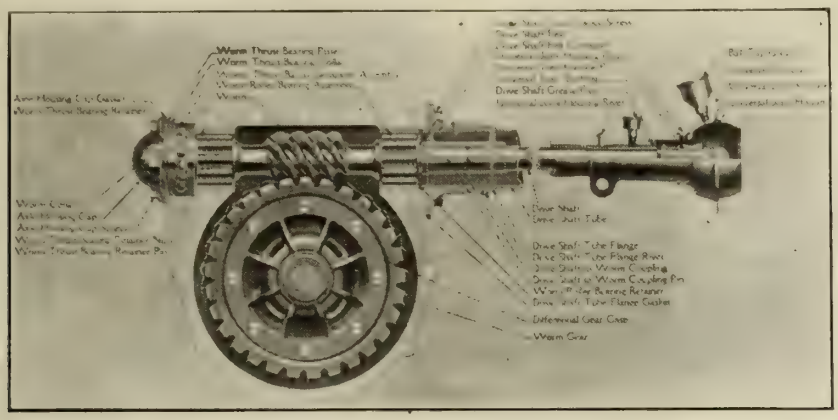

Fig. 11.—Sectional view through truck axle.

A careful check is made on parts entering each case, and the head of the team knows without question that everything is in place before the case is closed. The shipping building is a wonderful sight with its high roof and heavy duty crane. Tracks run up the complete length of the building, and the loading platforms are spaced to suit as shown at Fig. 9. Box cars are used for shipping, and the photograph shown was taken while box cars were in place.

Their method of receiving and sending out the smaller parts could well be copied by other firms. The idea is shown at Fig 10. On parts being received, they are sent up the roller incline to the distributing floor of factory and the man in charge makes a note of the time of arrival, number received, and so on. Should parts be leaving the main plant, for some of the other buildings, check is made of this, so that nothing leaves or enters the factory without a note being made of it.

The office staff must also be reckoned with, for they are well organized and work in close harmony with one another. While their work may not show in the shop, the year's total sales is ample proof of their activity.

A passing mention only is made of the first-aid department and welfare work. These are of the best and considerable money is spent yearly in order to keep the sections as modern and helpful as possible.

Making Trucks

In making trucks, several changes in plans have to be followed out. The rear end is entirely different, being a worm drive. Fig. 11 shows a section through this drive, and as all parts are clearly shown, we leave the reader to study same at his leisure. On the completed chassis, any body and special equipment can be placed, and includes the standard express and stake body, rapid delivery with canopy top, all-purpose combination body, end dumping, steel dump bodies, etc.

Fig. 12 shows a standard stake body, which consists of a regular platform and slatted side. When other styles of bodies are used they are made by outside body factories, such as the Commercial Motor Bodies and Carriages, Ltd., Guelph. The Brantford Carriage Co., Brantford; The Canadian Top and Body Corp., Tilbury, and Hay and Harding, Calgary, Alta.

To discuss all styles of body would occupy more space than we have at our disposal. There is the all-purpose farm body, the combination grain, freight and stock body, dump bodies for contractors' use, and so on. Specially designed chassis is also part of the truck, this being made by the Swedish Crucible Steel Co., of Canada, Windsor, Ont. According to what the truck will be used for, the frame and body equipment varies, but in all cases, a recommendation is made as to the shortest and longest body best suited to the frame. Fire trucks, equipped by the Bickle Fire Engine Co., Woodstock, Ont., are also made, these being of varied combinations, as to equipment of chemical engine, hose, etc. Then there is the semi-trailer, the passenger bus body, and other arrangements.

The same principle of manufacture holds good. Nothing is put into the truck which will not stand rough usage, and a gear ratio of 5 to 1, gives it a speed up to 25 m. p. h. without undue increase of engine's speed. In the main some of the operations are similar, so we will pass on to a few more figures regarding the Ford plant which readers can think over at their leisure.

The annual pay roll of the company is over $5,800,000 and to this must be added the millions disbursed as wages by the branches, and other manufacturers located in Canada who depend almost entirely on the Ford Co. for business. To keep the plant clean costs approximately $15,000 per month and the average wage is $6 per day. Over a period of ten years, the increase in wages per employee has gone up 214 per cent. During the fiscal year, 1921, the company purchased over $19,000,000 worth of material and supplies and have paid over $12,000,000 in duty during the past twelve years. In the last eight years the wage bill has totalled more than $32,000,000 and at present $1,500,000 a year is being paid in taxes. In spite of the massive proportions of this industry, everything moves like clock work, with the result that any visitor cannot help but be impressed with the fact that only a far-seeing mind could have conceived such a wonderful factory.

A great deal of praise has been given to the late Gordon McGregor and it has been well deserved, because he worked and brought the factory up from its infancy but has now passed on, and from our observation, the present organization will not only carry things along successfully, but as the years go on, a larger and more wonderful plant will result.

W. R. Campbell is first vice-president and treasurer of the Canadian plant; P. W. Grandjean, secretary and assistant treasurer; G. E. Dickert, plant superintendent; H. S. Pritchard, sales manager; W. J. Baxter, advertising manager; L. C. Wilkinson, service manager; W. R. Burgin, traffic manager, and W. E. Disher, purchasing manager.

MAKING LAMPS AND OTHER METAL PARTS FOR AUTOMOBILE TRADE

AT THE Canadian Lamp & Stamping Co., Ford, Ont., head, tail and dash lights are manufactured. This plant has a floor space of 30,000 sq. ft., is valued at $200,000, and produces about 15,000 head lamps, 8,000 tail lamps, and several thousand dash and rear stop signal lamps every year. Hub caps, and other metal parts for automobiles are made in the same plant, these running up into the thousands.

On the first floor the punching, blanking, and drawing operations are performed, and in making the reflectors for the headlights several drawing operations have to be gone through. Other general press work needs no further discussion in a general article of this nature.

Plugs, connections and bulbs, come from the States, and are assembled to the lamps on the ordinary tables, and packed ready for shipment. Before reaching this finished stage they pass through the regular buffing and polishing department, electro-plating section and enameling room.

A well-equipped tool room forms part of the plant and it is here that all dies and tools for production are made. Lamps for Ford, Overland, Gray Dort, Studebaker, General Motors, and Ruggles truck are made, and others are always being added from time to time.

Reduce Your Truck Costs and Improve Service

Explaining How to Keep Close Tab on Driver and Other Operating Expenses—Standardized System of Cost Keeping by Means of Simple Cards

"WHAT does it cost you exactly to run your truck?" If this question were put to the average manufacturer, owner of a single truck, it is very doubtful whether he would be able to give an intelligent rereduce his stock costs and better his ply.

Every truck owner naturally wishes to service as much as possible. What then is the answer? The first step is to find out the true cost of every item of motor truck expense. Without every item, the cost keeping system is useless, for you must have all possible leaks covered.

An accurate record of the daily performance of each truck should be kept, this including loading time, running time, available but not used time, etc. All such statement should be clearly and simply recorded, so that the system can be carried out without undue effort on the part of the truck driver.

Once let the operator understand you are watching the performance of the truck, and the savings effected will astonish you. Through the courtesy of G. M. Grant, of the Packard-Ontario Motor Co., Toronto, we are able to show a daily record sheet, also a record sheet for the month of March, both of which are from annual tests, and not merely filled in for the occasion. The Packard Co. have made an exhaustive study of truck costs, and use the National Standard Truck cost system, on all their work. They do so, because, as Mr. Grant says, "It has been developed to such a point that it is easily kept and is accurate in every respect."

Motor Truck Transportation

All conditions being equal the cost per day of a truck will vary with the miles travelled per day. It will increase as the daily mileage increases. The cost per mile will vary with the miles travelled per day. It will increase as the daily mileage increases. The cost per unit (for example, ton) will vary with different capacities, and the distance hauled. It will increase with an increased truck capacity. It will increase with an increase in hauling distance.

The cost per unit-mile (for example, "ton-mile") will vary with different capacities and the miles of truck travel per day. It will decrease as the capacity increases. It will decrease with an increase in daily mileage.

But what is the unit-mile and how is it figured? Suppose a truck travels from A to B a distance of five miles, and carries one ton. This truck has then performed five-ton-miles of work. If it carried three tons it would have accomplished 15-ton miles. Suppose it now returns empty to the starting point. It has run miles, but carried no tons, so there can be no ton-miles. This fact has caused most of the misunderstanding of this subject.

See page 6.

Owner and Truck Operating Costs

Truck owners may be divided generally into two classes: Those who haul for themselves and those who haul for others. The Chicago Tribune is authority for facts showing that approximately ten per cent. of the cost of doing business is represented in transportation. System states that the net profits of business do not average above eight per cent. The owner who keeps costs is in a position to reduce his transportation expenses and thereby increase his net profits.

DAILY RECORD, MONTH OF _____; HOURS IN WORKING DAY _____ FROM _____ TO _____ TRUCK NO. _____

| | OPERATING DATA | | | | | | | | | | | | | | | COST DATA (Posted to Form 3c) | | | | | | | | | | | | | | |

The man who undertakes motor truck hauling for other concerns must know his operating costs in order to fix a fair price for his services. Such records will insure adequate profits and he will be in possession of facts to justify any necessary increase in rates. Because operating cost facts tend to eliminate the hazard of an unexpected loss, the vendor of equipment on a partial-payment plan should encourage his customers to keep them. They will be added insurance that the notes will be promptly redeemed.

While the actual cost of operating a motor truck varies a great deal, the reasons for these variations can be easily determined. There are certain standard principles which should be used in estimating operation costs. Motor truck operating costs, either estimated or actual, contain two factors. The fixed costs must be paid regardless of how much or how little the truck is used, while the variable costs change with daily performance.

Fixed Costs

Money at work in a business is entitled to a fair wage called interest, which is usually figured at a certain per cent. of the money at work. Many truck owners consider the price of their truck and its equipment as money at work and so charge the normal "interest wage" against the truck as an operating expense. There is a growing tendency however, to omit interest as an item in operating costs. This is especially true to firms hauling for themselves, because they believe that dividends on any investment must come in the regular profits of the business. This rule, on the other hand, would not apply with equal force to firms running their own trucks to serve others.

The following conditions affect the daily or monthly amount of interest: Amount of investment, rate of interest, assigned book life of truck in years and miles and days in operation per year.

Taxes and License

These items vary according to the laws of states and cities, and are usually

levied with reference to truck capacity, total weight and horse power. Many forms of insurance have been developed to cover hazards incidental to motor truck operation. The yearly charge for insurance will depend upon the following conditions: Location, trade classification, protection deemed necessary by the owner, necessity for protecting merchandise carried in the truck, and requirements of partial payment plan.

Drivers and Helpers

The salary factor is frequently the largest single item of expense. It is usually considered a fixed sum, but variations may be expected on account of the following conditions: The business location and owner's policy, method of payment—salary, hourly basis, overtime, bonus and local labor conditions.

The duties assigned to laborers and helpers also affect the wage scale: For example: Do they serve only as drivers and helpers? Does one person serve in both capacities? Must the driver serve as a mechanic? or, Must the driver be a salesman and handle money?

Another point to be considered is: Do you use a public garage or house your truck in a part of some building? Does the rent include washing and filling with oil and gasoline? what is your accounting practice? Do you include charges for water, light, heat, interest and depreciation? Is there any overhead or administrative expense?

Occasionally the owner of a motor truck will allow it to stand unprotected or else use an old building, which is considered worthless. Under such conditions, owners usually refuse to make a garage charge and when making comparative estimates this fact should be taken into consideration.

Depreciation

As a reserve or sinking fund to replace a motor truck, this item is considered as a fixed charge when calculated on a yearly basis, and as a variable charge when calculated on a mileage basis. The amount to be written off in either case will depend upon the share of the total investment which is to be replaced by the fund thus established. The usual practice is to subtract the value of the tires from the total cost of the vehicle and thus arrive at the sum to be amortized.

The total amount to be depreciated, divided by the number of years, will give the charge per year.

Variable Costs

When depreciation is calculated as a variable charge, the life of the vehicle is estimated in miles, usually 100,000 and the amount to be depreciated is divided by this figure. The result is a depreciation charge per mile which, multiplied by the mileage of any period, will determine the reserve to be set aside for that period.

In estimating the cost of gasoline used in the operation of a motor truck, it is well to bear in mind that the actual cost will depend upon a number of things, among them being carburetor adjustment, ability and care of the driver, load, road, grade, traffic, delivery and climatic conditions, price of gasoline and amount of gasoline used for cleaning, but charged to the truck.

The cost of lubricating a motor truck is one of the smallest items of expense,

Total Cost to be Depreciated $ 4720 00 for Est. Life of 100,000 Miles = 4.7¢ Per Mile

Estimated Yearly Maintenance & Repair $ 850 00 for 10,000 Miles = 2.5¢ Per Mile

Tire Estimate Per Mile { Actual Life by Past Experience 10,000 Miles / Guaranteed Life 8000 Miles } 24 Per Mile

Battery Renewal Estimate Per K.W.H. Consumed

Fig. 4.—This cost record shows every item of importance and sums up the information given.

but nevertheless one of the most important in truck maintenance. Among the factors controlling this cost are price of lubricants, regularity of application and renewal and condition of vehicle and the design of the lubricating system.

Repair and Overhauls

This item, while usually not the largest, generally receives the most attention. It casts an immediate reflection upon the quality of the vehicle. Among the factors controlling it may be mentioned quality of materials, design and workmanship, load, road, and operating conditions, ability and care of driver, frequency of inspection and garage attention, line of business.

Among the factors affecting the tire cost are road condition, tire design and wheel alignment, and loading practice and driver's efficiency. Any estimated tire cost will depend upon the price of the tires, and the nature of the manufacturer's guarantee.

Having covered these essential points we will next discuss briefly the purpose of the system shown on the four forms. Large cards similar to Fig. 2 are bound together and there are sufficient leaves to keep the complete cost and operation data on one truck for one year. It is so arranged that each page represents one month's running. There is also a monthly analysis sheet as shown at Fig. 3, and a cost record sheet illustrated at Fig. 4.

At Fig. 1, we see the driver keeps track of his trips; on the reverse side of his form, he places any additional remarks, delays, weather, road conditions, accidents, etc. or anything that is necessary in the way of explanation. At the end of each day he turns in his slip to the office clerk handling the cost record and he or she, as the case may be, fills in the data on the card shown at Fig. 2. It is unnecessary to comment on the different columns, as they are self-explanatory.

From the figures shown on Fig. 2, form at Fig. 3 is compiled. Note how complete the information and how simple it is to find any desired item. The cost record, Fig. 4, shows the final analysis and as everything is clearly illustrated we leave readers to study all the forms at their leisure.

With each cost keeping set of forms comes detailed description, so that there is no confusion in this respect. As Mr. Grant, so aptly puts it, "When owners study and apply this method of truck operation and cost, they will reduce expenses and increase efficiency."

Makes Seventy-Five Thousand Sets of Auto Wheels Yearly

WITH A production of 75,000 sets of wheels per year, the Kelsey Wheel Co., Walkerville, are keeping a large percentage of the automobile factories in Canada supplied with this most important part of a car. The value of the plant is $860,000, and the factory covers over four acres. Property owned is more than 11 acres, so they have ample room for expansion if necessary.

The present number of employees is 292, and the plant is working right up to normal. The average weekly pay roll is about $7,700, and right from the raw material stage, wheels are produced at high speed. Where to start a description is rather difficult, for the parts are made in different departments, later meeting at the proper point for assembly.

The raw material is cut to proper width and length, then rolled in forming rolls until reaching proper shape. The joint is next welded, and after welding, the rim is finally brought to true shape on a machine built on the tire setter principle which is set at an angle for convenience. Tire carriers go through practically the same process.

The woodworking end of wheel making is very interesting. The spokes are first rough formed on a horizontal turning lathe, then they are mitred or beveled on a vertical machine having two knives set at the proper bevel. Leaving this machine they go to an automatic sander, after which they reach the first assembly bench. Here the spokes are assembled to the wooden rim, being squeezed into proper shape on a machine working on the principle of the tire setter. The outside of rim is next turned, then the metal rim assembled to the wooden rim.

During this procedure the hubs have been passing through the various machine operations, this consisting of regular turning, boring, reaming and drilling operations. Single and double-spindle turret lathes form the largest part of the tool equipment in the hub department.

There is quite an amount of sheet metal and fairly heavy stamping done at this plant, for in addition to wheels and tire carriers, they make a patented clip used on detachable tire rims. In the press department they have considerable money tied up in equipment and dies.

Painting Wheels

The method of painting the wheels is simple and very quick. The workman places the wheel horizontally over a spindle in an automatic paint-dipping machine, drops the wheel into the paint tank, then raises it above the paint. He puts on the power for a moment allowing wheel to revolve rapidly, thus throwing off any excess paint into tank. The operation is completed so rapidly that a wheel can be painted quicker than it takes to read this description.

The value of suitable carriers is pressed home to anyone visiting this plant. The carriers used are extremely simple consisting of band iron fastened together into the form of guides. One of these conveyors can be seen in the illustration showing interior of another wheel company at Chatham.

The shipping of this enormous quantity of wheels yearly is a problem in itself, but it is well handled, as the shipping facilities provided are splendid. Although a large percentage of the steel used in these products comes from the other side, the work of fabrication is 100 per cent. Canadian. Mr. Campbell is manager, while Mr. Fox handles the sales end.

Making Five Types of Cars At One Plant

Many Improvements in Manufacturing Methods Have Taken Place—Considerable Export Business Handled—Packing of Crates Watched Very Carefully

IT IS surprising how many changes and improvements can take place during a few years. On July 3, 1919, we published an article on the making of the Chrevolet motor car at Oshawa, but to visit the same plant to-day, and write the story is an entirely different proposition. Instead of speaking about one make of car you must mention five, viz., the Chevrolet "490", Chevrolet "F B," McLaughlin Buick, Oldsmobile and Oakland.

These cars are all manufactured under the name of the General Motors of Canada, with extensive plants at Oshawa and Walkerville. In order to avoid confusion, we shall consider the Oshawa plant first.

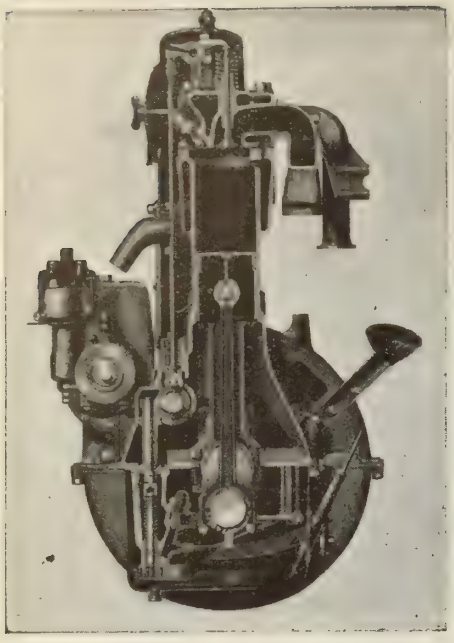
The proposition being so large, several buildings are required to handle each make of car. These consist of paint and trim shops, chassis assembly, final assembly, final test and export shipping building. Other structures are, body plant, radiator department, central enamel plant and closed body building. The total acreage covered is approximately 15 acres.

The number of employees engaged is 1927, and the average monthly pay roll is around $234,000. The daily capacity of the combined plants is 175 cars, of which about 50 per cent. are shipped to the following countries: Great Britain, Scandinavia, Spain, Greece, Northen Africa, East and West Africa, South Africa, India, China, Strait Settlements, South American Republic, Australia and New Zealand. In addition to cars, one-ton trucks are made at the Chevrolet plant. These figures will give an idea of the size and capacity of the combined factories. Next we will consider the actual manufacture. In some ways, the process is much the same on all cars, so we will treat the subject in a general way.

The Frame

First comes the assembling of the frame. The different members are drilled then assembled on special stands, pneumatic rivetting hammers being employed. Air hoists are used to lower the assembled frame on to a slow moving chain, and once they start on this line, the springs, axles and motor, etc., are assembled. In 1919 ordinary four wheel trucks were largely used for this work, but general use of the chain has been a wonderful improvement.

While the frame has been at the rivetting stand, and passing through the first stages of assembly, men directly across the floor have been putting finishing touches to the motors. This arrangement is carried out as far as possible on all makes of cars. When we speak of the motors being assembled, it is of course, understood that we refer to assembling the transmission to the motor, electrical units, carburetor, etc., because each of these themselves are in assembled condition, and it is really a final assembly to the engine that takes place. Once being bolted together, the now complete motor passes on to the department where the frame is being made into a complete chassis.



Showing bodies passing into enamelling ovens, shaping wooden body parts, early stages of body building, and building the wooden body frames.

Every Movement Studied

It will be noticed how carefully these initial steps are planned, and the same condition holds good throughout the entire group of factories. Every movement counts, nothing passes backward, and each workman has his own particular duty, being a specialist in that operation. Lost motion is reduced to almost the vanishing point, and naturally production soars accordingly.

The muffler, gasoline tank starting gear, underpan, drip pan, radiator, coil distribution tank, tire carrier, etc., are now assembled, after which the chassis is inspected, and all necessary parts filled with grease and oil.

Sectional end view of Mc-Laughlin-Buick Motors

From here it goes into a special paint chamber, spraying by air gun being the process. This gives it an even penetrating coat of paint, speeding up the operation at the same time. It only takes about ten minutes to paint a complete chassis, and after leaving this room it goes into a drying oven with a temperature of 180 degrees. In about 55 minutes out comes the chassis at the other end, dry and ready for further assembly.

Mounting Department

This section of the plant is referred to as the mounting floor, and here the car goes through various steps of assembly. The wheels with tires in place are put on the axles, the bodies are lowered through a hole in the floor above, having been previously assembled in the regular body department. Later we will describe this operation, but for the present will stay with the car on its road to completion.

The fenders, running boards, and aprons are added next, and by this time, it is looking more like an automobile. The final assemblers take hold of it and go all round and all through the car, putting everything in first class shape. Various adjustments are made, then the top is placed on the body. A final inspection is made before the car goes to the test department. During our visit in 1919, this final line of assembly had to push the cars along by hand from operator or operator. A chain now supersedes the manual labor, and quicker and better work results.

The cars next go to the test room, where every one undergoes a rigid road test before being passed O. K. Should a defect of any nature show up, it is removed at once, and another road test taken. This is kept up until the inspector feels the car is shipshape in every way, and good enough for his own use.

Starting with the bodies, here is the method employed in their manufacture. Down in the woodworking department all that is heard is the buzz of hundreds of wood working tools, each thoroughly up to date, and equipped with jigs or forms to guarantee that all parts made will be similar. These forms are very necessary, for many of the wood parts of a car are very peculiar in shape.

In this department are two machines well worthy of special mention. Wood is fed in from both ends, having been cut to certain length previously, and as they pass in, they are tongued and grooved and these joints coated with a thin layer of glue. Reaching the center, they are glued together at such a speed that you wonder almost how it happened, and in this way certain parts of the body are built up. The shaping of the door frames is also very interesting, the complete frame being placed in a form jig, and in less time than it takes to tell, is formed to shape.

The bending of the bows is also well arranged. These are made of maple ash, and are first steamed. They are then placed over a form, pressure exerted, and formed to shape. Several bows are shaped in the one form, then they are tacked together and placed in the kiln to dry.

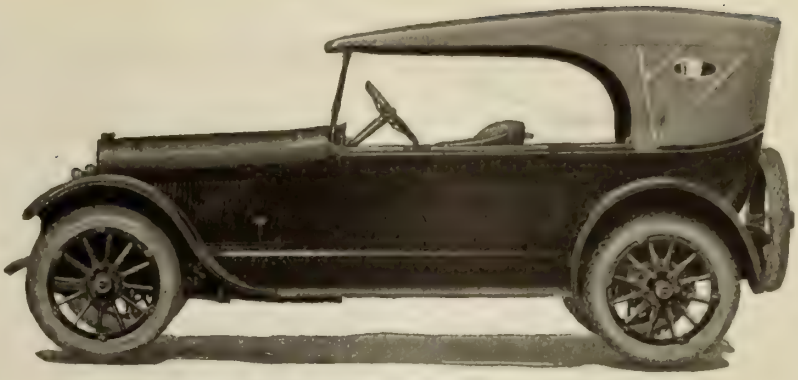
Leaving the wood working, we will consider a very vital operation performed on another floor. The back metal portion of the body is welded by oxy-acetylene torch to the two side portions, this forming the rear seat part of body of car. A special, yet simple holding jig is used, and the operator merely runs his torch and filler rod down the seams welding all three parts together.

We will next consider the method of assembling body. Everything is placed in a form, and at the start you would imagine they were building a small boat instead of a car body. In a remarkably short time however, a change is noted. Pieces match together almost like magic and soon we have a complete wooden framework. The next stage is the metalling of the frame work, that is, nailing on the sheet steel coating, and after this is done, the latches, doors, and all other small attachments are added. The body is despatched to the paint shop and then, when it is ready for mounting, it is sent to the upholstery department. In both the body building and upholstery work, the men work in teams.

An up-to-date enamelling plant handles the work of enamelling fenders, hoods, pans and such parts. They are first washed in a washing machine similar to that used in large restaurants, a cleaning compound is employed to remove all oil, stains, etc. This is a very important operation, for if the parts are not thoroughly cleaned, the enamel will not adhere to the metal. Great care is taken however, and after the parts leave the washer, the moisture is blown out of all seams by air nozzles. Should any rust stains show up these are removed with fine emery paper.

Next comes what is known as tack ragging, that is, the workman uses a pad with a little tack varnish on it, this removing any dust stains or grit. This having been done the parts are hung on hooks, over slow travelling bars, attached to a conveyor chain. Each style of part has a certain shaped hook, and these have been arranged to allow enough space between the hanging parts to prevent rubbing and allow clear flow of the enamel. The conveyor chain operating the movements of parts, moves

View showing plants of General Motors of Canada at Oshawa.



at the rate of 18 inches per minute, and there is 510 ft. of chain.

The pieces now dip down slowly into the first enamelling tank, rise slowly, allowing ample time for dripping. They pass up through a drying oven down into the second tank, up into another drying oven and repeat this performance at the third tank, coming out at the end of the line with a three coat finish of black enamel. From the time the parts pass through the washing machine until they reach the end of their enamel journey, only 2½ hrs. have elapsed.

The heat of the ovens is electrically controlled, and in order to safeguard against fire special precautions have been taken, including a Foamite installation. Even should a fire occur, it should be out in 20 seconds according to the methods of smothering flames employed. However, should the one method fail to function, they have another system of automatically emptying the enamelling tanks into outside storage tanks that would be sure to prevent serious damage.

To show the care taken to enamel their product correctly, here are a few features regarding the installation. The air in the ovens is changed every four minutes, and dipping tanks are cleaned out periodically, and all the air used is washed before entering the drying tunnels. Every morning, a workman goes over each bar on the conveyor chain, removing all dust and enamel which may be there. He uses a certain type of tallow on the rag, this preventing the dipping hooks from sticking to the bars. Every bearing on the conveyor chain is automatically oiled, and throughout the entire enamelling plant cleanliness is demanded, otherwise the workman must leave.

It is surprising to see how neat everything is, in a building where practically nothing but oils, paints and enamels are used. An idea of a month's requirements in this building are worth studying. Here are a few items. 310 gallons of cleaner, 283 gallons coal oil, 254 gallons reducer, 520 gallons rubber coat, and 1101 gallons of fender finish.

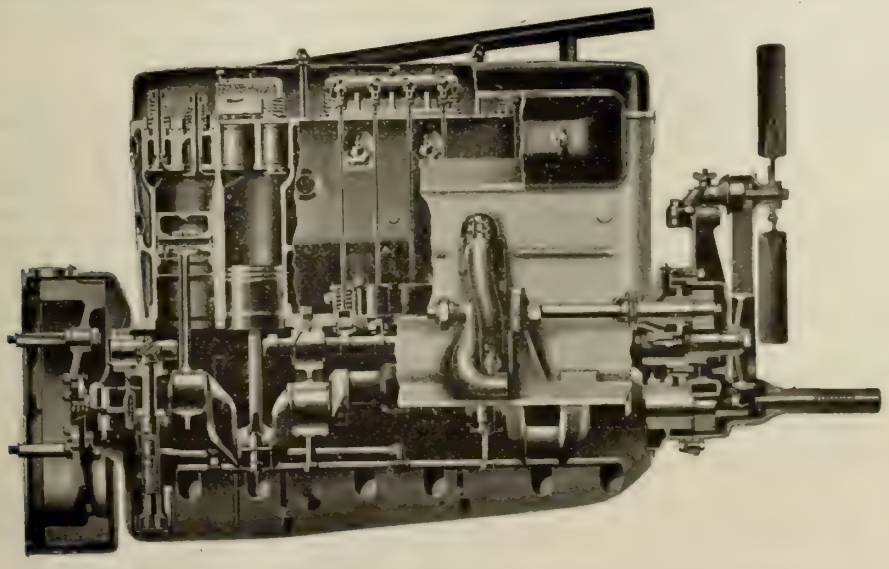
General View of New McLaughlin Special.

The enamelling ovens used for certain models of bodies in another part of the plant are very efficient. In this case the pieces pass through three horizontal ovens, and a slow moving chain carries them along. By the time the three coats have dried, a smooth hard finish has been secured. As the process is similar to the other enamelling, we will leave the matter at this point to consider briefly how other bodies are finished. Where an enamel finish is not desired, these have to be done by hand. Colors vary considerably, especially in work for export. The usual washing and rubbing down decks are employed, and as the process is covered in another article in this issue we will pass on to the car top.

Making the Top

Here again we find that a frame work is used to work from, and although a top looks a complex unit when completed, it becomes a simple operation when handled on a production basis. The operator could almost assemble it in his sleep. First come the bows and sockets, then the pads, stringers, back curtains, deck, front and back, then the finishing of the raw edge.

The Export Building



In domestic shipment the matter is fairly simple. If the destination is less than 100 miles, usually the car is driven over the roads, and if more than 100 miles, placed in a box car, and sent forward. Where export business is concerned, it is a very different matter, for in this case the car must be partially disassembled again, and boxed in a very careful manner. The General Motors Co. have made a study of their export trade, and have developed the packing end of it to a fine science.

In the crate making department, are piles and piles of wood cut to proper length. On long flat tables, the men nail the sides or ends of crates as the case may be, and these are forwarded to the main export shipping floor, which really consists of various platforms, in between which are railroad tracks. Huge cranes handle the boxes, but first let us start at the packing. Depending upon the make of car, and its destination, certain packing rules must be observed. Each team of packers know their duties thoroughly, and the man in charge of each team is responsible for the contents of the crate, so naturally he is extremely careful to see that all parts go in.

After being torn down as much as required, the parts are packed and firmly braced in all directions. Every square inch is utilized, and when completed, with the exception of the box cover, the novice wonders how on earth they managed to get so many parts into so small a crate.

This general story may not be absolutely similar for all cars, but in the main the process is the same, so that it is sufficient for the purpose of showing the present activities at Oshawa. The photographs scattered through the article show clearly some of the various operations and as the underlines are self explanatory, we will pass on to the Walkerville plant where the engines and several other parts are made for the cars built at Oshawa. The plant in Oshawa also has a machine shop where miscellaneous pieces are machined. Following is a list of executives responsible for the production of the various models:

President, Mr. R. S. McLaughlin; vice-president, Mr. G. W. McLaughlin; purchasing agent, Mr. E. W. Drew; factory manager, Mr. W. A. Coad; chief engineer, Mr. W. H. Moyse; export executive, Mr. J. B. Thomson; sales manager, McLaughlin division, Mr. J. H. Beaton; sales manager, Chevrolet division, Mr. Ross McKinnon; sales manager, Oldsmobile and Oakland Division, Mr. R. D. Kerby; executive in charge of central committee, Mr. C. E. McTavish.

Showing sectional view of McLaughlin-Buick Six Cylinder Valve-in-Head Motor.

Over 30 Models of Motors Made at this Plant

AT THE Walkerville plant, which covers ten acres, 981 are employed. The factory is a veritable mass of machine tools of every description, large and small, and in the case of the smaller tools about 90 per cent. are Canadian-made. In the larger machines however, about 95 per cent. are American-made tools, although these were largely purchased through Canadian dealers, so that in some measure at least Canada received the benefit.

The production secured at this plant is surprising, when it is considered that some 30 models of motors are produced.

That is to say, the same engines are used in some respects, but with certain additions the number of styles reaching thirty. This means that the production line is often broken up just when things are moving nicely, and the time expended in changing the tool equipment is quite a serious item. In spite of this drawback, approximately 3,216 motors are made per month, these being for Chevrolets, Oldsmobiles, McLaughlin cars, and General Motor Co., business.

The success of the plant is largely due to the thought expended in the segregating of the various departments. Once a piston enters its particular section it does not leave until it is a finished article, and when we mention that the piston department is only very small in comparison with the complete plant, it shows at once how well the machines have been arranged. There is absolutely no waste floor space. Every square inch is made to count, and this same arrangement holds true all over the plant.

To discuss at length the many interesting fixtures and operations would take a volume, so we will comment only in a general way, passing quickly from section to section.

On a large Ingersoll horizontal table continuous miller, four McLaughlin crank cases are milled. These are arranged in suitable jigs, so that the top and bottom, together with the gear case ends, and flywheel housing ends, are finished at one time. The crank cases are made of aluminum, and since adopting this method a high production rate has been secured.

To prevent any further breaking up of the production line than is absolutely necessary, the service division is kept as a department by itself. Nothing but outside service parts are completed, and one particular jig used is worthy of special mention. The operation is the reaming out of crank shaft bearings. Previously these were put in a lathe and bored, but it was very slow work. A new idea was adopted, this being a jig which simply held the cap in place as shown at Fig. 1. An air operated drill, with pilot reamer completes the tooling and the sketch shows clearly how the cap is reamed. The production time has been cut in more than four, showing considerable saving in operation cost.

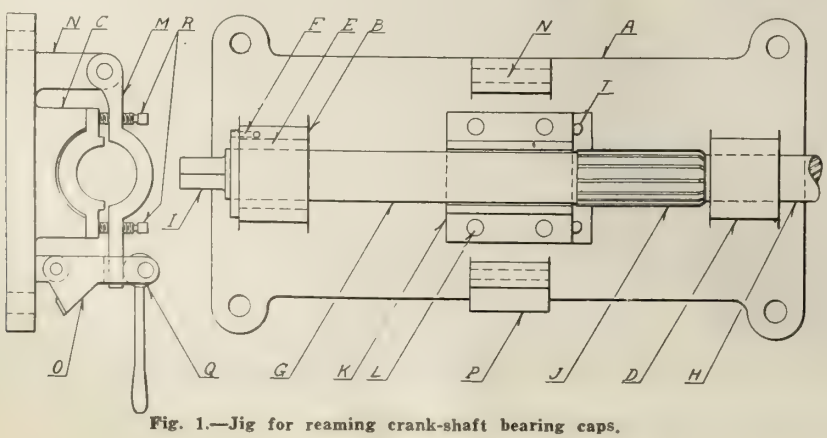


Fig. 1.—Jig for reaming crank-shaft bearing caps.

Making the Piston

In the piston department several special machines of their own design are used to speed up the work and bore the connecting rod pin hole, while automatic lathes complete the regular turning operations. Then there is the cam shaft and crank shaft turning and grinding departments, the connecting rod section, the gear cutting division, the cylinder line, the small part line, etc., all of which are extremely interesting, but which we will not dwell upon.

Balancing Section

A point on which they are extremely careful is the balancing of connecting rods, cam shafts, etc. Each part is balanced, first by itself, and in the case of the connecting rod, this part is also balanced after assembly to the piston. They are set up in jigs, straightened if necessary, weighed and balanced. The flywheels also go through a balancing process on a machine very similar to a vertical boring mill, holes being drilled at different points, until the dial on the balancing machine registers a smooth running flywheel. Another little incident which shows the care taken to make a first-class engine, is that the clutch shifter yoke receives a grind finish, and not merely a turning operation as generally occurs.

The assembling of engines is a very interesting process. First the valves and springs are placed in position, then step by step, in go the various parts. After the crank shaft is in place, the main bearings are run in, then disassembled and inspected. From this point on, the connecting rods, pistons, etc., are added, and another test is made. After the engine has proved satisfactory the bearings are again inspected, new gaskets placed in position, and a final test given after the clutch is assembled. Should the result be unsatisfactory, the engine is rejected, and must go through all the tests once more. Regular dynamometer stands are used in the final test, and the engine is subjected to the same conditions it would meet with if on the road.

When the clutch is being assembled to the motor, it is placed in a special jig which guarantees the location being correct. The starting motor is added and the engine must then run with starter motor in position. This guaran-

tees that when the inspector passed it, the starter was working O. K. and should anything occur between here and the assembly factory at Oshawa, it can be traced between these two points. It is very seldom however that anything occurs, and then carelessness is usually the cause.

To guard against wastage of steel, not to speak of poor machining, all tools are ground in one central tool-grinding room. Several tool grinders are used, and everything is sharpened to what has proved best practice.

Axle Department

The drop forgings for the front axles are made across the street at the Dominion Forge and Stamping Co., so the transportation between plants is very easily handled. The milling of forked ends of axles is done on a horizontal axle miller, and all faces are machined simultaneously.

From this point on the steering knuckles are added, with bushes, cones, king bolt, clip, tie rods, etc. In order to make sure that everything is in proper line, a special master jig is slipped down over the assembled axle, and from certain gauge points the workman straightens and adjusts the parts until everything lines up.

The rear axle division is carried on in a very careful manner, and after the various units have been machined and assembled, a test in a noise-proof chamber is made until all parts work smoothly under tests, which the car would experience on the road. To show the extent of work handled by these two axle plants, following are figures of an average month's production. Front axles 4,159; rear axles 1,655.

Heat Treatment

Naturally, the front and rear axles, including gears, etc., require heat treatment. A very well arranged building is used for this work, and Fig. 2 shows a sample record card used to keep tab on the parts passing through this department. Several sets of hot rolls are also included in the equipment, these being used to rough to size the rear axle shafts. Lead baths, and other usual heat treatment equipment are also installed.

Tool Room

To meet in with the requirements of the machine shop a large tool room forms part of the plant equipment. Here are found the usual types of tools including die sinking machines, etc., and the variety of dies and production tools handled in a month is surprising. Back of this department again is the engineering division who design tools and fixtures according to Mr. E. J. Mahar, the general superintendent, who is the power behind the throne so far as production is concerned.

Mr. Mahar does not take stock in efficiency experts. In fact, he says, they had a small army of them around at one time, but now that they have got rid of them things are going not too bad. Every man in the shop seems to know him personally and he has a greeting for everybody. We remarked upon this, especially in such a large plant, and his answer was that this condition was caused through his letting the men feel this was their shop as well as anybody else's, and that he was behind them, always providing of course they did the fair thing. A simple policy no doubt, but it works out to perfection, for we were much impressed with the friendly spirit displayed by all departments.

Reclaim Room

A very important section in this plant is the reclaim department. Should any small part be defective, down it goes to this room, even if the damaged part is only a small portion of an assembled unit. The man in charge is an experienced inspector, and removing the defective piece he replaces it with a new part, tests it, gives the complete part his O. K., and thus salvages what would otherwise be scrap. This room alone saves the factory many thousands of dollars every year. In the same department there is also a man who does nothing else but check up fixtures, castings, etc., this employee being an experienced layout man. He also checks up new patterns, or in case of dispute about poor castings, the old pattern in use at the foundry. By so doing, the firm have a careful check on the castings coming into the plant, and any foreman who believes the castings are not coming to his department correctly, can get this man to check the matter thoroughly.

In conclusion, we comment for a moment on the neat stock rooms which are centralized as much as possible. Everything is binned and tagged, so that the store keeper can tell from his card system the exact amount of material in his room. Nothing is left to chance in the factory, and as Mr. Mahar says, "We are always looking for ideas. Some of the best we have already received, came from the greenest of our men. At least they were green to start with, but once a man shows an inclination to not only advance himself but production as well, then we see that he does not lose out for his aggressiveness."

PARKER MOTOR CAR CO. LOCATE IN MONTREAL

One of the most recent additions to the number of automobile factories in Canada, is that of the Parker Motor Car Co., Ltd., of Montreal, P. Q. The Parker car has been undergoing development tests for the last four years, but only in the autumn of 1921 was active work toward the organization of the company commenced. The president of the company is Brig.-General Sir Alexander Bertram; first vice-president, W. H. Parker, of Montreal, former manager of Chipman (Canada), Ltd.; second vice-president, H. A. Bertram, sec'y-treas. of the Canadian Die Casting Co., Ltd., Montreal; sec'y-treas., Kenneth F. Dewar, industrial councillor, Montreal. The following compose the board of directors: Sir William Price, Frank W. Ross, T. J. Dillon, Thos. Craig, Hon. Rudolph Lemieux, Col. J. A. Scott, and C. F. Doutre.

The first cars produced had built into them all the road-going qualities that are featured in the regular cars although these machines were built for exhibition purposes. The cars were first shown at the Windsor Hotel early this year. A factory has been secured at Longue Point, an eastern suburb of Montreal. The building was originally erected by Messrs. Carron Bros. for the manufacture of farm engines and machinery. It is served with a railway siding from the Canadian National Railways. The plant is all on one floor, the roof being of saw-tooth construction. The Parker Motor Car Co. have 65,000 square feet of floor space. The length of the building is 850 feet.

At present the car is largely an assembled one. The company intends taking on the manufacture of some of the units in the near future. As sales increase, it is planned to undertake manufacturing on a large scale. The car is built mostly in Canada to-day. Up to the first of June only ten cars in excess of the exhibition cars had been built and sold. Another ten cars will be built in June. The manufacturing schedule for the following three months is: one a day in July, two a day in August and three a day in September. Very little machinery for assembling the cars has been installed. Mr. J. A. Wright, the automotive engineer, is paying a great deal of attention to individual assembling and testing, and has not turned his efforts towards quantity work as yet. James Vernon is the assembly foreman, and H. C. Doran is the shop foreman. The second vice-president, Mr. Bertram, in addition to his general executive duties, acts as purchasing agent and mechanical superintendent.

NUMBER OF MOTOR VEHICLES REGISTERED IN CANADA BY PROVINCES, 1914-1921

Rapid Increase in Production and Registration

In Seven Years, Registration of Automobiles Has Increased Over 700 Per Cent.—Total Capital Invested Is Very High and Fuel, Wages and Other Miscellaneous Expenses Show Large Figure

HOW MANY automobiles were made in Canada during the past five years? How many firms were engaged in automobile manufacture during this time, and what was the total capital invested? These; and many other questions are of supreme importance, and it is only by careful and detailed investigation that figures can be secured. The Dominion Bureau of Statistics at Ottawa, have since 1917, covered the automobile and allied industries in a very thorough manner and from a huge mass of data, we have selected the following, because of their extreme interest to our readers.

The number of establishments classed as manufacturers of automobiles in Canada in 1917 was 11, in automobile accessories 24, and in repair work 497.

The total capital invested in these industries was $35,780,677, apportioned as follows: in automobiles $28,192,858, in accessories $3,155,893 and in repair shops $4,431,926.

The total salaries paid were respectively $1,376,692 in automobile plants, $266,147 and in plants making accessories and $334,780 in repair shops.

The value of materials used in manufacturing and repair work in each case was, automobiles, $35,585,820, accessories, $3,788,308, and repairs, $1,961,773. The total value of production and repair work for all classes was $66,053,207, of which automobiles amounted to $54,466,273, accessories to $6,495,868 and repairs to $5,091,066. Classified according to purpose, the number of different classes of cars recorded in the census returns was, touring cars 80,544, runabouts 5,502, closed cars 1,165, delivery wagons 1,231, club roadsters 561, trucks 117, and not classified 556, or a total of 89,676 cars.

In 1918, the number of establishments reported under the previous mentioned heads, automobiles 9, automobile accessories 24, and automobile repair shops 673. The capital investment in the whole industry was $36,977,979, classified as automobiles $27,796,303, automobile accessories $3,370,771, and automobile repair shops $5,810,905. Of this total, land buildings and fixtures amounted to $6,880,781, machinery and tools to $5,291,206, materials on hand, stocks in process, etc., to $16,403,940, and cash, accounts and bills receivable to $8,402,052.

Fuel and Miscellaneous Expenses

The outlay for fuel amounted to $347,810, and the miscellaneous items of expense or overhead charges amounted to $8,896,639. The cost of materials used in the industry including those in raw and partially manufactured state was $37,313, 296. The total value of production and repair work for all classes amounted to $72,286,040. The number of cars of each class was as follows: touring cars 61,258, closed cars 1,502, open runabouts 3,750, chassis 5,286 trucks and delivery waggons 2,515, others 66, or a total of 74,379 cars.

In 1919, the various provinces were considered by themselves and following is the way the figures shaped up:

Provinces	Automobiles	Auto Accessories	Auto Repairs
Alta.	0	2	96
Brit. Colum.	0	6	78
Manitoba	0	3	81
New Bruns.	0	0	84
Nova Scotia	0	0	49
Ontario	11	26	600
P. E. Isl.	0	0	2
Quebec	0	3	162
Sask.	0	2	134
Canada Totals	11	42	1,236

The amount of invested capital was also sub-divided for each section of the industry, but it is sufficient in our case to give the total which was $56,943,018, this covering automobile, auto accessory, and auto repair shops.

About 12,139 were employed in this work, with a wage total of $15,389,742. The fuel consumption, including coal, coke, gasoline, fuel oil, wood, gas and other similar fuels, reached quite a total, being $72,683 for Canadian goods, and $430,788 for imported material.

Other miscellaneous expenses such as rent, power insurance, advertising, etc., totalled $8,993,804 in automobile plants, $1,041,215 in accessory plants, and $1,633,216 in auto repair shops.

Cost of Material Used

The cost value of materials used includes freight and duty, and the quickest method is to give the information in table form.

FOR AUTOMOBILES

Steel bars and tubing	$ 1,264,305
Malleable iron and steel castings	2,329,830
Lumber	3,207,308
Bodies	9,851,443
Parts and accessories	11,927,533
Tires	12,388,576
Motor truck parts	4,779,141
Trimmings	2,612,770
All other materials	3,329,809
Total	$51,690,715

FOR AUTOMOBILE ACCESSORIES

Brass and copper tubes, rods and castings	405,549
Steel bar sheet and castings	806,632
Lumber	1,314,839
Malleable and grey iron castings	91,240
Bolts, nuts, rivets, tacks, etc.	589,487
Top materials	1,319,872
Glass and celluloid	313,192
All other materials	1,380,628
Total	$5,221,439

Parts and accessories for repairs totalled another $4,360,810. The selling value of products for the year in all factories already mentioned totalled $101,196,706.

The total number of cars was 87,835 with a valuation of $68,929,820.

Shows Steady Increase

The rapid expansion of the automo-

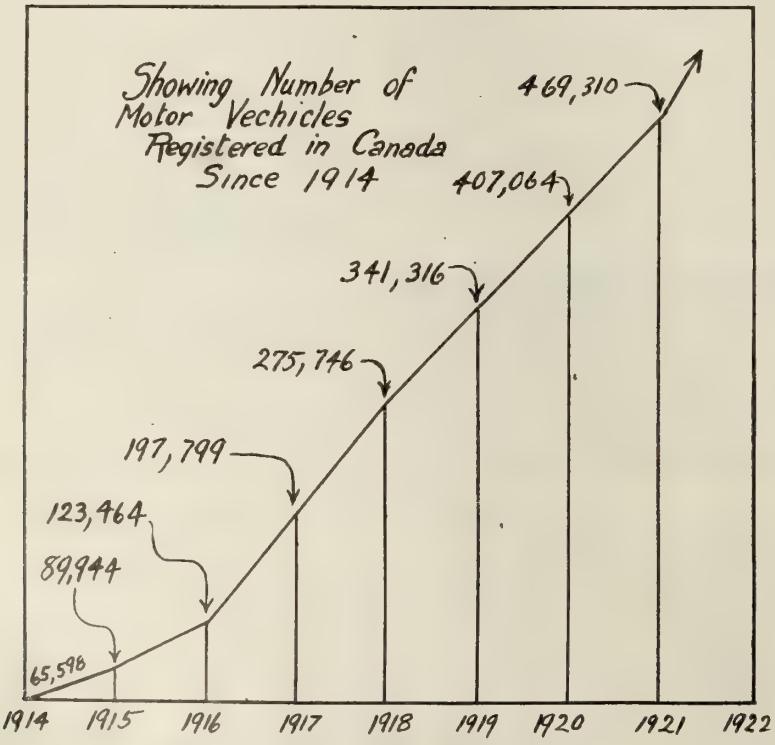

Chart showing motor vehicles registered since 1914.

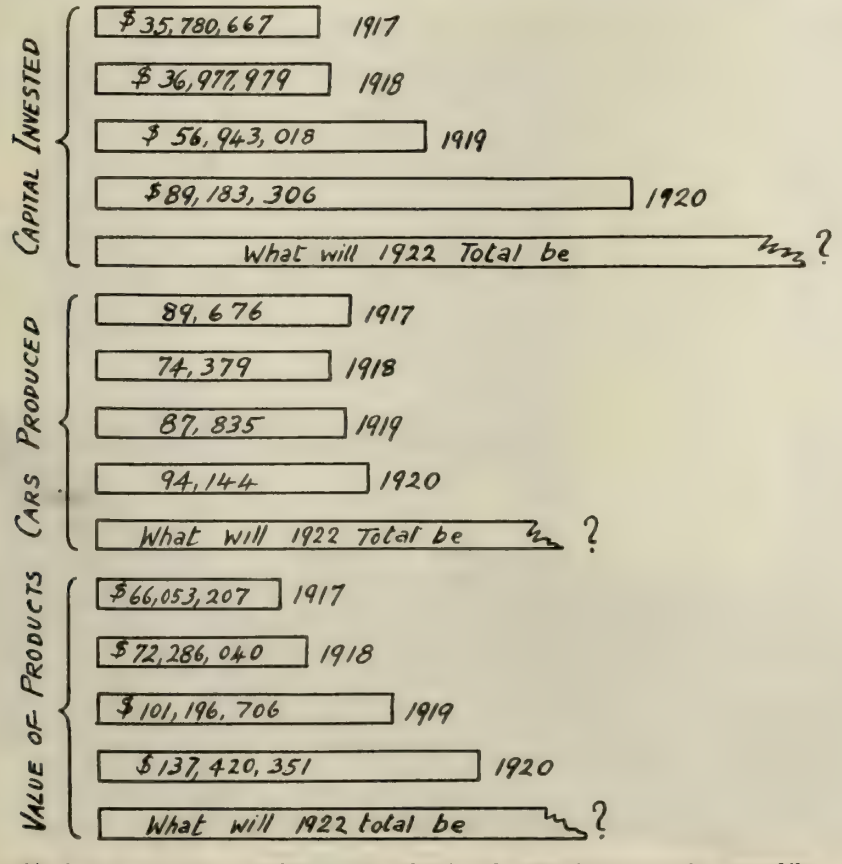
bile industry continued during 1920. In each of the three branches, considerable development took place, and the total value of production in all classes equalled $137,420,351, or an increase of $36,223,645. This was made up as shown on the following table:

	1919 $	1920 $	Increase over 1919 $
Automobile Manufacturing	80,619,846	101,465,846	20,846,000
Automobile supplies and accessories . .	8,571,890	19,361,882	10,789,992
Automobile repairs	12,004,970	16,592,623	4,587,653
Totals	101,196,706	137,420,351	36,223,645

The number of plants manufacturing cars increased from 11 to 17, in 1920, two being in the province of Quebec, the other fifteen in Ontario. Automobile supply plants increased 20 over the 1919 total, 14 additional factories coming to Ontario. The investment in capital for 1920 was $53,906,506, an increase of $18,956,767 over 1919.



In salaries and wages the total was $13,331,084, an increase of $3,618,296. The total cost of materials used in the automobile industry during 1920 was $84,432,444, an increase of nearly $24,000,000 over 1919. The total value of production jumped to $137,420,351. Pneumatic casings, tubes, and solid rubber tires manufactured in Canada during 1920, were valued at $40,177,119.

The rapid increase in the use of automobiles has shown up plainly in the registration figures, for between 1914 and 1921, following is the increase: In 1914, 69,598 cars were registered. In 1921, 469,310 automobiles were accounted for, of course many of this total were imported cars. The number of automobiles produced, including pleasure cars, and commercial trucks was 94,144.

All figures given are based on the years ending Dec. 31, so that the final report for year ending Dec. 31, 1921, is not yet in complete form. However, sufficient has been shown to illustrate the development of this most important industry to Canada. To compare 1920 with proposed 1922 production, simply glance over the various articles in this issue. The Ford Company alone expects to turn out 55,000 cars, so that when you add the lot together, a very satisfactory total is secured. With improved machinery and better manufacturing methods the automotive industry has advanced rapidly, and the future is still bright for further development.

On May 24th in 16¾ hours between dawn and dusk at the English track called "Brooklands" an Aston Martin motor car, driven in turn by three drivers, covered 1,275 miles, an average of 76 miles an hour.

A total of 23,997 automobile licenses have been issued in the Province of Quebec from March 1 to May 15, as compared with 17,000 for the same period last year, according to a report of the Provincial Treasurer's Department. According to officials there has been less speeding recorded on highways and generally more prudence on the part of car owners and chauffeurs, resulting in a considerable decrease in the number of accidents compared with previous years.

This chart shows value of products, cars produced, and capital invested in the automobile industry in Canada.

SPECIALIZE ON AUTOMOBILE PARTS, SHEET METAL OR STEEL

TO describe the size and varied activities of Pedlars Ltd., at Oshawa, Ont., in a brief article of this nature is extremely difficult. As the present issue is chiefly devoted to the automobile industry, we will touch only on the automotive work being completed at this plant leaving a description of the many other lines manufactured for some future occasion.

A word or two regarding the plant itself. Of the latest design, every modern improvement has been incorporated. Each portion of the factory is well supplied with light and the equipment has been arranged according to a previous well thought out plan. All the heavier presses are placed down one side of the main floor, the other miscellaneous tools being arranged according to departments.

In the heavy stamping section of the plant, we find enormous toggle presses, capable of drawing out such heavy stampings as transmission cases, fenders, etc. The assortment of dies used, would open the eyes of the average mechanic. Apart from their size, they show clever design and painstaking experiment, before present production was obtained. Only the best drawing steel can be used in the construction of these fenders, etc., for otherwise the parts would crack when being drawn and become useless.

Over on the other side of the floor we find peening hammers which remove any slight dent or mark in the products being made, and in this portion of factory are also found the smaller presses and other metal working tools.

Up on a gallery floor, certain parts of the fender are made, also gasoline tanks, mufflers, etc. Considerable spot welding is done in the making of fenders, this work being completed on specially constructed forms.

In the making of gasoline tanks, both, round and rectangular, the main body is first formed and shaped, soldered, then the heads soldered in. Every operation is in sequence, with the result that there is practically no lost motion.

When making mufflers, the same careful method of planning operation is followed out. In fact Mr. Murphy, the superintendent of entire plant, rather prides himself on this feature of all departments. Each man has his own particular duties to perform and although not what could be termed an all round tinsmith, he becomes a specialist in one operation, which is really what is needed in a plant of this kind.

Leaving the manufacturing end, and coming to the shipping room we find ideal arrangements here as well. Careful check on all parts going out and coming in is made, not only for quantity, but quality. If a piece shows a defect, that is, should the defect occur between the

(Continued on page 68)

Durant "Star" Will be Made at Leaside Plant

Toronto Factory Now Operating at Capacity of Over 700 Cars Per Month—General Features of Present Models—New Car To Be Constructed On Slightly Modified Design

DURING the short period of activity at the Leaside, Ont., plant of the Durant Motors, since the inception of the Canadian company, rapid progress has been made in organizing the plant for quantity production. With the exception of the coverings for the upholstering and cab, and a few minor details, no attempt has been made here to manufacture any part of the car, and the work at present is almost exclusively confined to the assembling of the Durant Four and Durant Six in various models. About 350 hands are now employed and the output has reached 30 cars per day. Some general idea of the car may be had from the following description, of the model B-22:

The motor is of Austed design with specially constructed overhead type of valve, fully incased. Pistons have a stroke of 4½in. in a bore of 3¼in. The motor will develop 70 h. p. when operating at 3,000 r. p. m. All bearings are automatically lubricated. The flow of gasoline is controlled by the Stewart Vacuum system to the carburetor, from a 16-gal. tank at rear of car. The radiator is of the cellular type, the water being circulated by a large capacity impeller-type pump.

Worm wheel steering gear is used with an 18in. wheel of walnut and aluminum centre. Ignition is obtained by Auto-Lite Igniter, driven by helical gears from the cam shaft. Starting motor acts on flywheel through Bendix drive.

A feature of the frame construction is the tubular backbone rigidly secured between the two cross members of the chassis. The incorporation of this member, which also serves as an exhaust muffler, adds considerably to the stability of the car, preventing distortion of the chassis frame and virtually eliminating all possibility of racking and squeaking of the body.

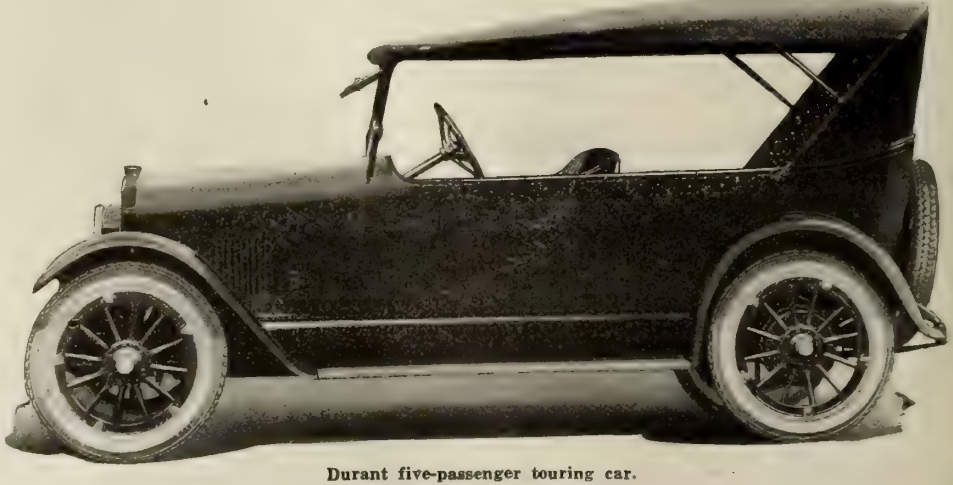
Timken front and rear axles are applied, the former being a drop nickel steel drop forging of I-beam design. The rear axle is semi-floating with pressed steel housing and driving through spiral bevel gears. Sliding gear transmission is used, with 3 forward and reverse speeds. This is mounted as an independent unit. Brakes on the rear wheels are 14in. dia. with 2in. bands and are external contracting and internal expanding. Both front and rear springs are semi-elliptical and made of specially treated steel. Spring eyes are fitted with bronze bushings.

The steel portions of the body are made from 22 gauge stock. These parts are imported from the States and subjected to a pickling and cleaning process to prepare them for the various coatings of filler, paint and varnishes. The original coating on the sheet steel parts contains a certain percentage of rubber to provide an adhesive surface for the succeeding coats. During the entire finishing process careful attention is given to the temperature of the different drying ovens and likewise the rooms in which the bodies or cars are left to dry. In regulating the temperature of the different ovens allowance is even made for atmospheric conditions as these will materially affect the coated surface. The flow method is used for the final varnishing of the car body, after which it is placed in a large dark room for the last drying; this usually being for a period of two days. No unnecessary traffic is allowed in this room so that the mirror finish will not be affected by the presence of dust particles.

The upholstering is of genuine hand buffed leather over extra grade curled hair. This work is all carried out at the plant as every piece is fitted separately.

The New "Star"

For several months the engineers and designers have been engaged on the plans and specifications of the five-passenger car that will be placed on the market at an approximate cost of $620. Owing to the unavoidable delay in getting started on the new building it is anticipated that this new car will not be available for some time. The addition under consideration for the construction of the "Star" will be a three-storey steel and concrete building 600 ft. by about 200, fully equipped for mass production. In connection with this new development it was stated that a separate plant will be erected by the Autolite Company for manufacturing the electrical accessories used in the Durant cars.



The general design of this car will be on the lines of those now made by Durant, incorporating all the improvements used on the other models. Continental engines will be used but with a slightly altered drive. The initial effort will be an assembly proposition with all parts specially made for this particular car. The piston displacement will be 152.1in. and the engine will develop 35 h. p. at 2,500 r. p. m. The inlet and exhaust manifolds are made with one common wall which serves as a hot spot to facilitate vaporization of fuel; carburetor is Tillotson type.

A combination pressure and splash system of oiling is used, the oil passing under pressure through the hollow cam shaft to the main bearings. The clutch is of the single plate type and similar in design to those used on other Durant cars. The rear axle will be Timken conventional semi-floating banjo type, fitted with spiral bevel gear giving a reduction of 4⅞ to 1. Ten-inch brake drums are fitted to rear wheels with internal brakes and external foot brakes.

A special feature of the Durant cars is the accessibility to all parts of the mechanism as in the majority of cases all parts requiring adjustment or possible repair are arranged so that operators can make changes without disturbing any adjacent parts of the machine.

IMPORTS INTO CANADA

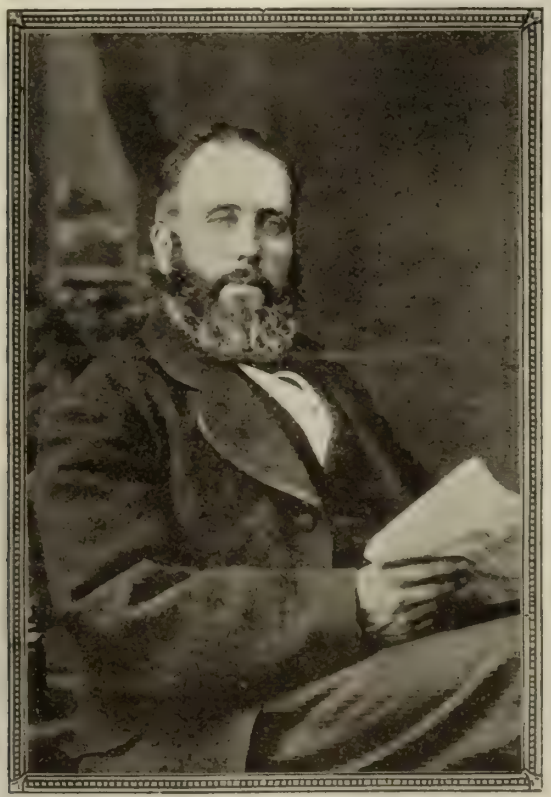
During 1918, 16,118 passenger automobiles were imported into Canada. Following are the figures up to 1921; 1919—6,475, 1920—10,805, 1921—5,907 Trucks showed up as follows:—1918—964, 1919—1,744, 1920—2,274, and 1921—1,706.

Durant five-passenger touring car.

Business Founded Over *Three* Generations Ago

Plant had its beginning in blacksmith's shop—Production of cars now reaches 7,500 a year and factory has capacity for 15,000 should demand increase.

Manufacturing division No. 3 which is located at center of city

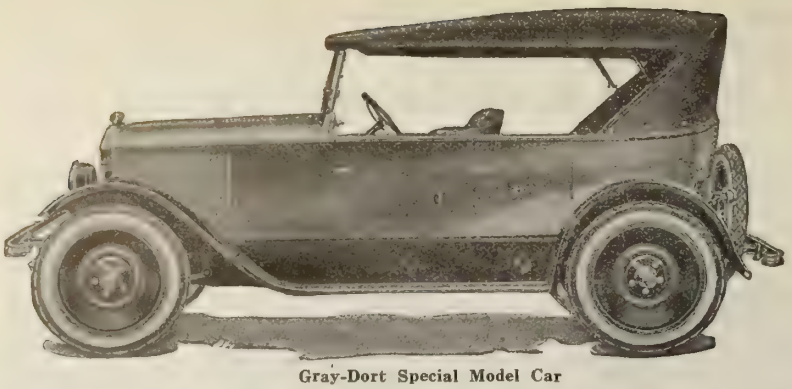


TO APPRECIATE fully the advancement which has taken place in the plant of the Gray Dort Motors, Ltd., Chatham, Ont. one must go back three generations, to the time before the railways spread their network of lines over the country, to the days when two million people lived in Canada. It was in these days, fourteen years before Confederation, that the Gray Dort organization had its beginning.

In 1853, William Gray came from Scotland and settled in what is now the city of Chatham. Here he opened a small blacksmith's shop to make vehicles. In less than seventy years the blacksmith's forge has developed into a gigantic automobile industry with a plant valued at $1,500,000 and a floor space of 400,000 sq. ft.

In 1883 William Gray was unfortunately injured in a railway accident, and after his death, his son Robert took over the responsibility although only 21 years of age. By hard work and close application, coupled with natural ability, the company developed, and in 1898 became a limited concern. Up to 1915, wagons, carriages and sleighs, had been the standard products, but in 1915 the decision to build automobiles was arrived at. Where people had been purchasing buggies, now they wanted automobiles, so it was decided to embody and add to their modern manufacturing methods, making possible a car at a reasonable price.

For two years Mr. Robert Gray had been studying the automobile industry in the States, and in 1915 he became allied with J. D. Dort of Flint, Mich., who, like the Grays, had been making and selling buggies. This briefly was the start of the present plant which has employed as high as 800 men, and produces some 7.500 automobiles per year. The plant however has a capacity 15,000, should the demand increase to that point.



Both Robert and his son William M.

Wm. Gray the founder of the business. He started as a blacksmith, but soon blazed the trail in the automotive industry.

Robert Gray, president and general manager. The business end of the organization receives his closest attention.

Gray-Dort Special Model Car

Gray are men worth meeting. They have grown up with the business, know every angle of it, and are keenly interested not only in the plant itself, but in the welfare of their workers and the civic life of Chatham, generally. However, as it is the mechanical phase of this industry we are chiefly interested in, we will pass on to the making of the car.

First, we find that practically all parts are made in Canada, with very few exceptions, where the parts cannot be obtained. For example, the springs, axles, tire carriers, top bows, transmissions, radiators, tires, trimming, gasoline tanks batteries, and many other parts are all made in Canada.

The complete plant consists of three separate factories. In the main building the cars are assembled and tested, and the machine shop, paint department, and enamel plant are also located in this building. In another factory the bodies are built, while in the third plant all sheet metal parts such as engine hoods, fenders, side apron, etc., are completed.

In the latter mentioned factory we find a full complement of sheet metal machinery, including presses, shears, trimmers, benders, and expensive dies. The routine of the operations is carefully watched the result being that the quality of work produced is very high. In the machine shop in the other factory miscellaneous parts are drilled, milled, etc., and in every case a jig is used in order to secure interchangeability.

The wood working department is exceedingly interesting. Again we realize the value of jigs and forms, for all parts are kept standard by this means. The door frames which are made of maple, are cut to shape very quickly, because they are placed in forms, and the operator does not need to worry about the shape. He knows they must come right. This same condition holds good all through the department. Nothing is left to chance. Several bending machines are used in this section, and the usual process of steaming the parts to be bent is followed out. After bending, they are locked in their forms, and placed in the dry kiln until thoroughly seasoned to shape.

Body Building

The experience gained in carriage building stood this firm in good stead when they went into the making of automobiles. They have a master form for each body and into this is gradually assembled the wooden framework. Next comes the placing of sheet steel over the wood, to be followed later with the trimming, or upholstery.

W. M. Gray, vice-president and assistant general manager of plant. He specializes on production.

The metalling, in other words, the attaching of sheet steel to the body, also the doors, is accomplished on suitably shaped stands. When assembling the woodwork, adding the metal to bodies, also upholstering, the men work in teams. The body during assembly passes along in one direction so that it is a steady and progressive movement. The greatest care is taken in all these steps, and after each operation, the body is inspected by the man in charge of team in order to make sure everything is O K.

Painting the Car

This firm is exceptionally particular about the finish of their car. The smaller parts such as fenders, hoods, etc., are enameled and baked, but on the body itself hand painting is carried out. Special trucks are made to support the bodies while they are being painted, and fortunately they are well supplied with floor space for drying purposes. In order that the process of painting will be clearly understood, we give the method in detail.

First the wooden part of the body receives a wood priming coat, and is allowed to stand until dry. The metal part is next washed and cleaned, several different cleaning mediums being used. A metal prime is now applied and usually the body is allowed to stand four days until thoroughly dry. The next step is slushing after which the body is puttied. After standing a day the next operation is sanding down. Leading comes next in order, then oil rubbing. Color varnish coats are next applied, two or three being put on according to conditions, and of course drying time is allowed between each coat. They are again rubbed down on the rubbing deck, then a finish coat is applied. The Flocote brush is used in all cases with the exception of the wood priming coat, and when being painted, the bodies are mounted on special stands with suitable troughs surrounding them.

Standard colors are generally applied, but on special models a different finish is made, although the steps are practically similar. The chief point of interest is the care taken throughout every step. On the rubbing down deck, the men keep at it with pumice stone, water and the rubbing swab, and until every gritty spot is removed, nothing is considered O. K. The training obtained in the carriage making days is too deeply ingrained to allow them to rush a body through with undue haste. Production is very essential and they secure it, but not at the expense of the body finish.

(Continued on page 74)

Here we see what is known as manufacturing Division No. 1.

Modern Factory Produces Many Cars

WITH A plant valued at $350,000, the Studebaker Corporation of Canada, Walkerville, Ontario, produced 3,069 cars during 1921. The work is practically assembly, painting, and testing, but 200 are employed on this work. The factory is well arranged, and briefly here is the procedure.

The frames come from the United States in their raw state but are rivetted at the Canadian plant. The springs come from the Dowsley Spring & Axle Co., Chatham, so that this part brings Canada a revenue. After chassis is assembled it is painted in the usual manner by air gun, and when dry, the assembly line begins.

The sequence of operations when assembling any automobile are very similar, but special mention can be made regarding the arrangement of storing various parts entering the car. This has been carefully thought out, and every part is handy to the workman assembling his particular portion. When the time comes for the tires and wheels to go on the chassis, they come down a chute from the floor above and meet the assembly line at the desired point. The tires have all been inflated, and are ready to place on the chassis before passing down this chute.

The radiators are made in Walkerville by the McCoy Co., and the tops are also made by two Canadian concerns. The motor comes from their Detroit plant, also several other parts going into the finished car. Wherever possible they purchase parts in Canada, and the Canadian percentage would run about 30 per cent. or more of the finished car.

The other operations entailed are similar to what has already been explained in other articles in this issue, but the following figures will be of interest. The total floor space occupied is 120,000 sq. ft., and the average monthly pay roll is about $12,000. The organization is well balanced, and upon completion of a car, so far as assembly is concerned, an exacting road test is gone through before a car is finally passed. The factory is modern in every respect and very handy to the railroad, as can be noted from the illustration of their Walkerville plant. This is called plant seven, as they have several other factories on the other side of the line.

The Canadian company is under the control of the parent corporation, and the officials are as follows: Mr. A. R. Erskine, president, Mr. M. F. Wollering, vice-president, manufacturing, Mr. L. J. Ollier, vice-president, sales, Mr. N. R. Feltes, treasurer, and Mr. J. E. Spence, secretary.

The immediate direction of the Canadian company is under Mr. W. G. Palmer, sales manager; Mr. E. B. Mackie, production manager, and Mr. A. F. Fuerth, assistant treasurer.

EDMONTON ACTIVITIES

"IT IS RATHER DIFFICULT to secure complete information showing the extent to which firms in this locality are working on automobile work," says John Blue, secretary of the Edmonton, Alberta, Board of Trade. "Two or three of the firms are well equipped and organized to give pretty fair data," he continues, "but there are several others that scarcely know what they are doing in this business. They are running the repairing of automobiles and manufacture of auto parts in connection with other work, and find it impossible to separate the one from the other in order to give satisfactory statistics.

"I find that we have six firms in Edmonton employing altogether about eighty men. They are as follows: Imperial Brass and Iron Foundry, manufacturing pistons, cylinders, fittings for tops, wrist pins, bearings, etc. They employ about twenty men and have about $50,000 invested, turning over about $6,000 a month.

"Edmonton Auto Springs make and mend springs, producing about one hundred springs a week. As I understand it, they import the steel and make the springs here. Wm. Fane, with an investment of about $20,000, employs about fifteen hands. He manufactures truck bodies, tops, auto wheels and, in fact, does any wood-work in connection with a motor car. He reports a growing business, with more than he can do. He expects to do $40,000 worth of business this year.

"Masse Electric Co. manufacture batteries. They have a plant worth about $10,000, employ six hands and expect to manufacture six hundred batteries this year.

"The Edmonton Auto and Carriage Co. manufacture tops and bodies for cars. They employ about eight hands, and do about $2,000 worth of business per month. A particularly flourishing industry is managed by Nichols Bros. They are founders, but manufacture bearings, pistons, piston rings, bushings and housings and also do any repair work on a motor car. They have an investment of about $60,000 and employ about eighteen hands. Of course there are a large number of carriage and auto repair shops, but I have found it very unsatisfactory to get information from them.

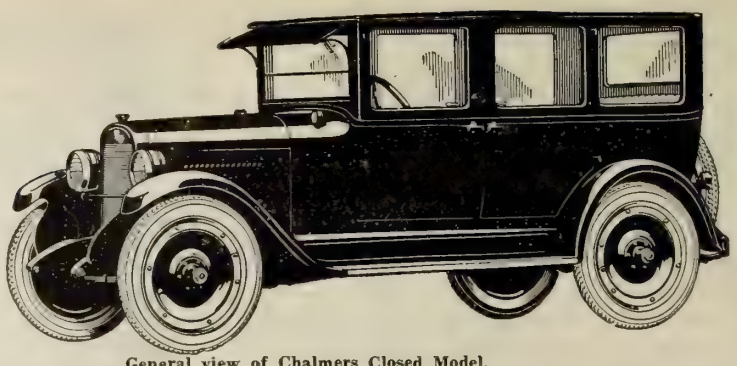
"According to a return prepared by the Bureau of Statistics very recently, capital invested in plants for automobile repairs in the Province of Alberta is estimated at $2,710,464, in 315 establishments; the wages paid in these establishments is $603,000, and cost of materials $945,897. On making a calculation of these for Edmonton, I think it would be safe to take between 33 and 35 per cent. as representing Edmonton's share of these statistics."

BRANTFORD ACTIVITIES

THERE ARE THREE CONCERNS in Brantford, Ont., who manufacture parts for automobiles, according to W. H. Wood, manager of the Brantford Chamber of Commerce. They are as follows:—The Brantford Carriage Co., which manufactures bodies; the Brantford Machine & Tool Co., which makes jacks and H. V. Morris & Co., who manufacture a tire boot.

The Brantford Machine & Tool Co. employ about nine men. The extent of business handled each year is approximately $18,000. The value of their equipment is about $15,000.

General view of Studebaker plant at Walkerville, Ont.



THIRTY CARS A DAY AT CHALMERS MOTOR

WITH A normal producing capacity of thirty cars per day, the Chalmers Motor Company of Canada, Windsor, Ontario, are busily engaged assembling their various types of automobiles. They have a modern plant in every respect which is well arranged and is 300 by 50 ft., two stories high. While the work is principally assembly, a good percentage of material used in making the car is purchased in Canada.

The material for Chassis frame is purchased outside, but assembled at the plant in the usual manner. It is then painted by the air-gun process, and after drying starts on the assembly line. The axles, motor wheels, gasoline tank, cowl, etc., are added in proper sequence, the body dropping down on the completed chassis, at the proper stage of the assembly.

After completion, every car is given a running test on grooved wheels set in the floor, these being driven by a motor in regular manner. The rear wheels of car are placed on the grooved test wheels, and rear axle undergoes an actual test while on the floor. Once the axle has proved to be running quiet, the road inspector takes the car out for a test drive. Every part is carefully inspected, and of course during the assembly stages, periodical inspections are given.

The bodies come into the factory in a finished condition, with the exception of the final varnish coat. This is applied in the usual manner at the Windsor plant. The motor used in the car comes from their Dayton, Ohio, plant and is thoroughly tested before shipment.

General view of Chalmers Closed Model.

SHERBROOKE ACTIVITIES

SHERBROOKE, Que. Speaking about the automobile industry in Sherbrooke, J. H. Brosseau, secretary-treasurer of the Board of Trade, remarks as follows:—

The Canadian Connecticut Cotton Mills, manufacturers of cotton tire fabric, when fully equipped will represent an investment of $5,000,000. In 1920 this concern did a business of $7,250,000, and had on the pay roll 950 employees. At the present time the number of employees is 600. They are doing a business for the year of about $5,000,000. The prospects for this industry are looking brighter for the future. This is the largest cotton tire fabric factory in Canada. The maximum number of employees will be 2,000 hands.

The Pressure Proof Rings Ltd., are manufacturers of piston rings for automobiles, launches and tractors. They also manufacture pressure proof aligning gauge, etc. This plant represents an investment of $30,000. The total amount of production for the year 1921 was about $40,000, and gave employment to 15. The prospects for 1922 are very encouraging.

The Panther Rubber Company Ltd. make rubber goods, moulded goods and sundries, such as automobile rubber mats, etc. This concern represents an investment of $300,000, but the automobile accessories amount to about $20,000 per year. The prospects are much brighter, and they are employing at the present time 75 hands and running full time.

There is also the Red Arrow Tire Ltd., of Quebec, which is a new concern, with the plant ready to start manufacturing rubber tires. This plant should do a business of about $300,000 per year and give employment to about 50 hands.

WINNIPEG ACTIVITIES

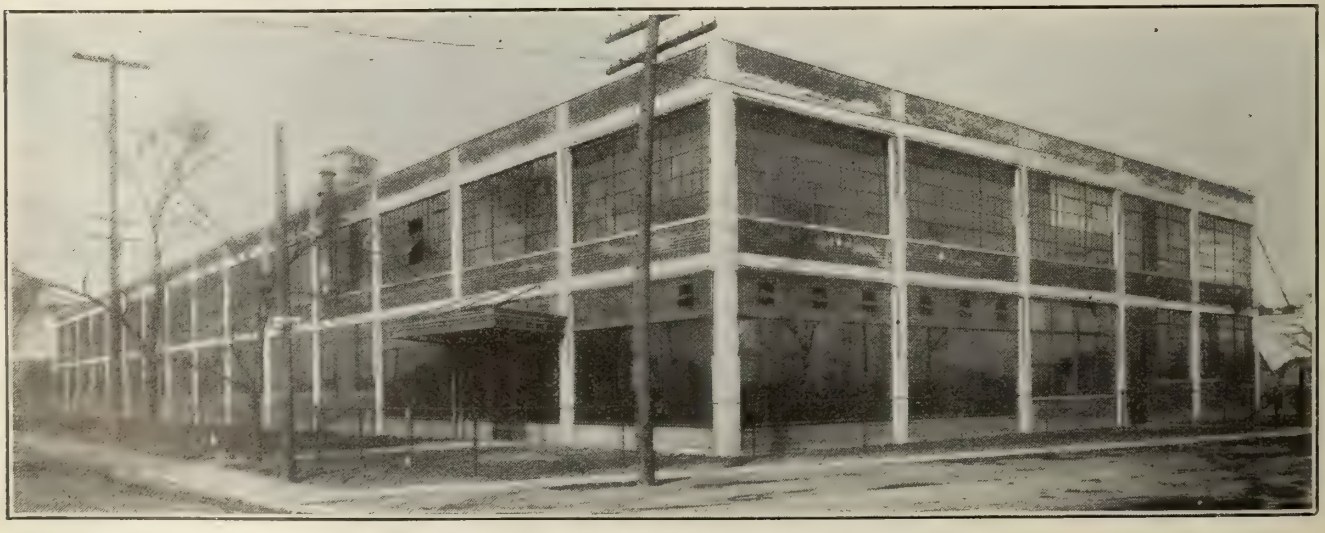
"WE FIND THAT THERE is very little manufacturing of automobile parts carried on in Winnipeg. Most of what is manufactured is handled as a side line. It is almost impossible, therefore, to give any idea of the amount invested in the manufacture of these particular products," says J. M. Davidson, of the Winnipeg, Man., Board of Trade.

The Winnipeg Motor Cars Co., mentioned on the following list, is just in the process of organization, and no cars have yet been turned out. The largest single industry assembling cars, is the Ford Co., but we are advised that none of the parts are manufactured here. Following are firms interested in the automobile industry in Winnipeg:

Bodies: Western Truck Bodies Co., Hulse Mfg. Co., Auto Body Works, Lawrie Wagon and Carriage Co.

Radiators: Hulse Mfg. Co., Rolfe Radiator Co., May Radiators, Ltd., Winnipeg Auto Radiators Co., Guarantee Sheet Metal & Roofing Co.

Tops and trimmings: Winnipeg Top and Trimming Co., O. E. Wood, J. Murray & Co.



Steering Devices: "Made-in-Canada" Steering Device Co.

Tire Boots: Porcupine Sale Corporation.

Signals: Universal Auto Signal Co.

Automobiles: Winnipeg Motor Car Co.

Batteries: Canada Dry Cells, Burgess Batteries.

General view of the Chalmers Plant, Windsor, Ontario.

Rigid Inspection One of Rules at this Plant

Parts Purchased From Outside Sources Are Tested Before Leaving Place of Manufacture—Further Test Given At Hamilton Factory—Jigs and Fixtures Are Extensively Used

AT THE National Steel Car Corporation, Hamilton, Ont., they have a truck making plant of which they are justly proud. As far as possible, parts are made in Canada, but like many other firms engaged on automotive work, they use American units, their production rate being too low to allow them to specialize in the making of all parts going into the truck.

However, although they find it impossible to manufacture all parts, they see to it that all purchased material passes rigid inspection. For example, the motors have to pass an S. A. E. test before leaving the factory in the States. This includes a curve sheet showing the performance of the motor under load. When a shipment of engines are about to be sent, some competent man from the National Steel plant goes down to the engine factory and witnesses the tests. This means they are sure of the quality of the motor.

The same close check is taken of all other imported parts, and although someone may not be visiting the supply plants at all times, tests are made in the home factory to make sure the quality is there. In addition to this, the American factories have their own inspection systems, etc.

No attempt will be made to discuss the source of supplies, nor will we enter details regarding the makes of the carburetor, transmission, etc., for this can all be secured from the regular specifications. Enough to state the axle is worm driven, carefully designed, and that all steels entering into their construction are tested for strength, a maximum factor of safety being allowed.

When designing the truck, the engineering department figured each unit carefully, and until all parts were made of ample strength, work on the truck was not commenced. The wisdom of this move has proved itself by the confidence displayed by the engineers in the finished article.

Improvements are always being considered, and while we were there, the engineers were installing additional comfort for the driver. In fact, this is one of their strong beliefs, that the driver of a truck can tell of its value, and for this reson they use the slogan, "Ask the driver—he knows."

The springs used on the truck have an elastic limit exceeding 190,000 pounds per sq. inch, with ten per cent. elongation. The shackles are made of drop forgings instead of cast steel or malleable iron, the type used being considered much stronger. The gear ratios vary, three being provided for 1 and 1½ ton trucks, four for the 2, 3½ and 5 ton vehicles. The road speed with governed motor is, 1 ton, 32 miles per hour, 1½-19, 2-15, 3½-13 and 5-12.

The capacities of trucks range from one to five tons and the equipment, such as body, etc., depend upon what the vehicle is going to be used for.

Actual Manufacturing

Leaving the question of imported parts and coming to the work performed at the Hamilton plant, we find that the production methods are well thought out. Everything is arranged in sequence and after the rough castings are received and have been thoroughly inspected, they are sent to the machine shop in lots that will give a certain length of run. This means that the setting up time on jigs, tools and other various fixtures, will be only a small percentage of the actual machining cost.

A jig room is separated from the rest of the machine shop, and all fixtures with their tools are placed in suitable compartments, ready at a moment's notice. All castings are machined in jigs, nothing being left to chance, and particular attention has been given to the design, so that castings can be placed into fixture without preliminary grinding operations.

Should milling be the operation, multiple jigs are adopted in order that a number of parts can be completed at one time. After milling, the finished surfaces are used as gauge points when placing the castings in the drilling jigs.

Figs. 1 and 2 show one of the drill jigs used. This is for steering column and pedal shaft bracket, and in Fig. 1, we see a close up of the part itself and the jig. A taper key holds the casting in place and once it is put in the fixture, all holes shown are drilled before leaving. This is made possible by the unique construction. In Fig. 2, we see the four holes in flanges or fastening base being drilled simultaneously. The other operations are complete on a different single drill press.

The same procedure applies to the drop forgings which are now in their own plant, of which may be mentioned all the different shackles which support the bearing springs. It is very important that these be made drop forgings, as a casting with a blow-hole would be detrimental to the truck.

The pins for the shackles, etc, are machined from hexagon stock on a production basis, heat treated in the forge shop and ground to close limits. Heating of pins, spring clips, etc., is made in the presence of an inspector who makes sure that final structure comes up to specifications. The heat treated parts are scleroscoped to further ensure against poor parts being used.

All material before it is used on the motor truck production floor has to pass an inspection bench in order to make sure nothing but correct material goes into the trucks. Reamed holes for pins, bushings, etc., are gauged with plug gauges, and the pins with snap gauges, with a "go and no-go" limit.

Fig. 1.—Close up view of part to be drilled, also jig for same.

Fig. 2.—Drill jig in actual use.

INSPECTORS' SIGNATURE

Fig. 3.—Showing style of inspection report used in National Steel Company's plant.

The efficiency of the machine shop has been brought to a point where the amount of material rejected through faulty machining is very small and the motor production floor has practically no trouble in assembling the different parts. The frame parts are drilled to jigs as well as the castings, so that there is seldom any reaming necessary to assemble the castings to the frame. In regard to holes for rivets, they are drilled to size and reamed on the erection floor in order to secure a first class job all through.

Assembly Floor

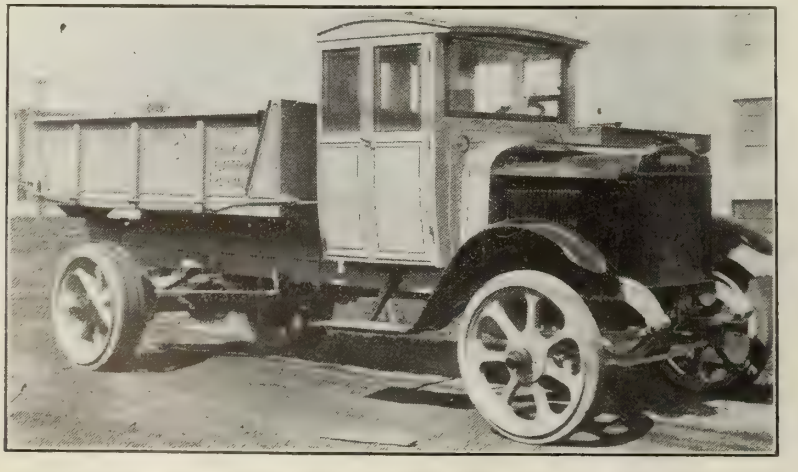
On the assembly floor, everything is built up step by step, and as far as possible, such assemblies are made at the side of main floor, in order to shorten the time for completing the truck on main erection floor. Having assembled the motor to frame, with all electrical units, body, etc., the truck is taken out on an exhaustive road test. This is continued until the inspector is satisfied that all parts are functioning properly.

M. Blomberg, motor truck engineer, for the National Truck Co., is largely responsible for the data contained in this article as he conducted the writer through the plant.

Mr. Newman, is now sales manager at the Canada Metal Co., Toronto. He comes from Montreal, having considerable experience in this class of work.

Have Well Laid Out Plant in London And Are Working To Full Capacity

WHEN the Ruggles Motor Truck Co. built their factory at London, Ont., they combined modern plant construction with architectural beauty. The office is splendidly designed and creates a decided impression on anyone approaching the factory. Yet it is directly connected with the factory, so that efficiency is not sacrificed for the sake of good looks.



The plant is built in one unit, but is planned with a view to future extensions. The power house is in a separate building, and this is also designed to take care of future requirements.

The actual cash invested is $335,000, and in addition they are carrying inventory and plant machinery to the value of approximately $350,000, so that the total investment is really about $700,000.

The floor space is 40,000 sq. ft. and at present about 150 are employed.

These figures are given by J. Bridge, general manager, and he further states that they are working to full capacity. The average monthly pay-roll in London exceeds $18,000, and on the present basis of production their annual output will exceed 1,000 trucks, composed of four sizes, 1 ton, 2 ton, 2½ ton, and 3½ ton.

The annual turnover of approximately $2,000,000 represents a cash return of Canadian labor and materials of slightly over $800,000.

Showing a popular type of truck built at the London plant.

The plant is very well lighted, and down a portion of one side of the floor is the frame assembling department. The various members are drilled, then riveted by air hammers in the usual manner. On the other side are store rooms where parts are carefully kept in bins. Further on, we follow the regular routine of assembly, parts being added until the truck is completed. After being painted they enter drying ovens, staying there until the paint is properly baked on to the metal.

The Continental motor is used, this being made in Detroit, Mich. In some cases, the Herschell-Spillman motor is placed in truck, these coming from North Tonawanda, N. Y. Bosch high tension magnetos are part of the equipment, also the Brown-Lipe three and four speed transmission, clutch and control. The Clark internal gear drive is adopted as standard practice for the rear axles.

Depending upon the use to which truck has to be put, bodies are made accordingly. They do not make these at the London factory, but have made arrangements whereby any desired style of body can be attached. The photograph accompanying this article shows one style of truck which is very popular.

Following is list of officers at the London plant:—President, F. W. Ruggles; vice-president, A. T. Little, (of Robinson & Little); treasurer, John Pringle, (formerly manager of Bank of Toronto); general manager, John Bridge; sales manager, W. E. Finnegan; purchasing agent, P. A. Manross, and production superintendent, Chas. Austin.

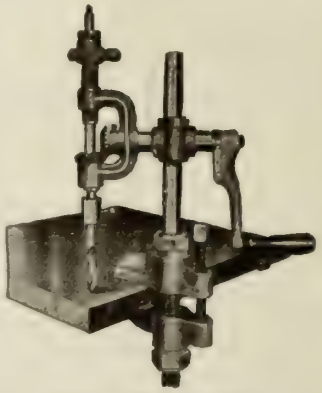
Garage Must be Able to Handle Any Emergency

Motion Pictures Show Operations in Service Garage—Comparing Equipment and Efficiency of Different Establishments—Courtesy an Essential Factor—The Operating Pit

IN A RATHER likeable movie play that has been featuring during the last few weeks, two garages are made the scene of considerable action. It does not seem necessary, of course, that there should be a great deal of equipment in sight in either one.

The general scheme of things seems to call for little else than a gas tank and pump. The garages appeared to be located opposite each other on a prominent road and naturally a price war developed and when the margin of safety had been passed, one of the garages went out of business, temporarily at least, as a strategic move. The expected happened. The remaining garage man cooked his own goose as the result of excessive charges and poor service and when he had become thoroughly disliked by patrons, the other garage re-opened, advertised stability of prices consistent with costs, and courteous, efficient service. They simply drove the other people to the wall.

The point in the play that seems to get a laugh every time is that which emphasizes a tendency on the part of the garage men to charge exorbitant prices for indifferent, ridiculous service, and that, what may appear from the outside to be a garage, really has no equipment to make it worthy of the name. The principal tools are the two hands and the nimble wit of the owner or operator. Moreover, the greater the air of mystery about a fake institution, the higher the rates for service.



Equipment and Courtesy

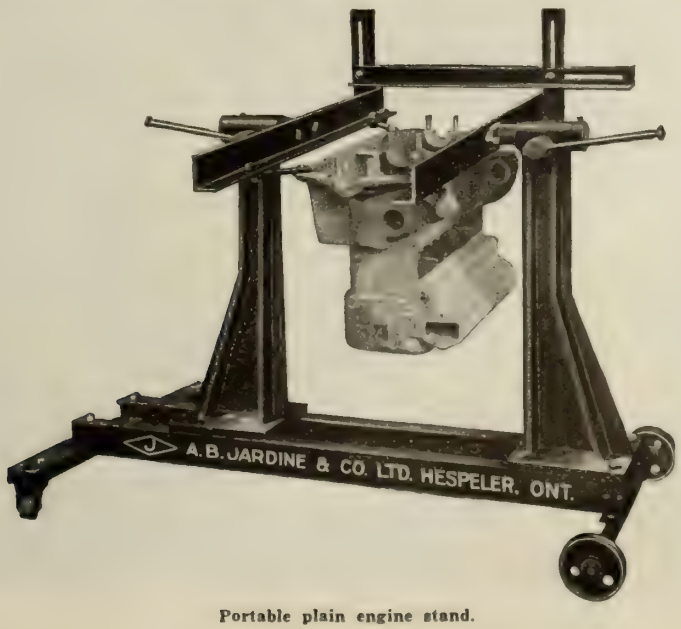
In the movie referred to, the fact was emphasized that the garage or any other business that backs up its equipment with courtesy and efficiency is the only kind that will have stability of existence. The ability to handle any emergency in the least possible time and to send the patron away pleased is the strong point in the garage business. The mechanical equipment is, of course, important. There is some difference of opinion as to what it should consist of. One man will say he could not do without a lathe, another will declare that he is in a position to get done outside what little lathe work is required from time to time. In the matter of cylinder grinding, it is found in some towns that there are local machine shops equipped for this purpose and hence the garage man sometimes feels that this lets him out.

An Operating Pit

Local conditions seem to alter cases. In a city of some 18,000, there is a garage with an operating and storage floor 90 x 140 feet. The mechanical department for repair purposes probably occupies 50 x 90 feet. There is a pit, covered with heavy plank when not in use, from which workmen may operate with comfort on the underworks of a car, instead of crawling underneath. This pit is about two feet deep, the same width and in length will accommodate five cars of any size at once. Above this part of the floor, a light conveyor track, with chain block hoists, is installed. While the owner is a strong believer in the portable floor crane he finds the above plan suits the purpose better when crane service may be required for more than one car at the same time. This equipment includes a portable crane which has a special base for floor service or may be placed on a truck for emergency wrecking service. He also has the truck for that purpose and his equipment further includes cylinder and valve grinding machinery, a rapid tire changer and an electric battery recharging outfit. Needless to say there is air and gas service and the floor is laid out with good drainage facilities for car washing operations.

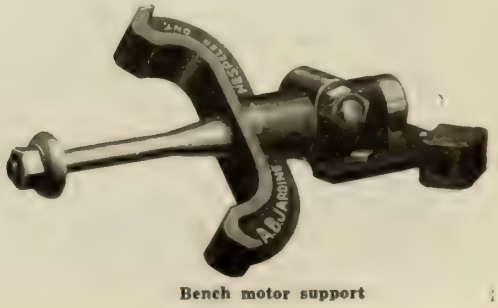
This garage has one floor only, carries the agency for the Studebaker, has storage room for something like eighty cars and is owned and operated by a skilled mechanic. It is not his first garage and

Hand drilling machine.



he pointed out that while he has eliminated some machinery, as not always necessary, he supposed he would be adding to it from time to time. The garage has a large display front.

When the storage end of the business is a desirable feature, and it is especially so in large cities, the two story garage has come into prominence. Here elevator service is essential when space limitations or other handicap will not permit of driveways or escalators at any easy grade. The hoist or whatever it may be, when it has to be operated by patrons, must be fool proof.



Manufacture of Equipment

The manufacture of garage equipment is an industry that has not developed altogether along exclusive lines. The production of some equipment works in well with regular lines upon which the

Portable plain engine stand.

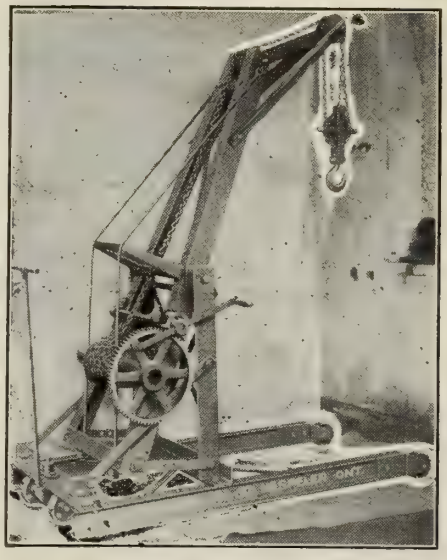
Bench motor support

Improved Machinery and Methods Helps Them Secure Production

AT WALKERVILLE, Ont., is located the Gotfredson Truck Corporation plant, where G. and J. trucks are produced. The factory is located in the heart of the automobile industry, and close to the steel plants, this enabling them to secure the various units and steels required without delay.

The present factory equipment has a capacity of 3,500 trucks a year, which is the number that will be built at the end of the present production year. Further increases in production are expected, according to statements from the management. The company is under conservative management, the president being Mr. Benjamin Gotfredson, who has developed the American Auto Trimming Co. to its present high standing. The policy is never to indulge in hurry-up methods to meet heavy orders. The absolute dictum of the management is that each truck must leave the factory well equipped to stand the battering and abuse most trucks are certain to endure. Extensive machine shops have been installed which permits of doing work correct to the thickness of a ten-thousandth of an inch. Improved modern production machinery makes for efficient and economical manufacturing. The accessibility of the Walkerville plants is another point in the company's favor. These are situated directly across from Detroit, and the G. & J. buildings are directly upon railroad sidings. Special loading docks expedite the loading of raw materials and the shipping of the finished product.

A complete line of trucks is made, including every model from one-ton speed truck, to heavy duty five-ton jobs. Almost every practical body design has been standardized, so that truck buyers can get this important part of their equipment at a distinct saving. Transportation engineers supply free the information as to what chassis and body are best suited for every trucking operation. An innovation so far as truck factories is concerned is the monthly service inspection policy which the company began about a year ago. Under this system, owners can bring their truck to any factory branch, or the factory itself once every month for inspection. Factory experts thoroughly test out the truck and advise what measures are necessary to maintain it at its highest efficiency. Speaking about this system the company says:—"This has proven a boon to owners who have seen slight troubles transformed by unscrupulous garage men into mountainous repair bills, and the popularity of the system is evinced in the manner in which owners never fail to take advantage of their monthly inspection. It also saves money for the owners because they only require a driver for their truck, leaving adjustments, etc. to the factory.



"The importance which we attach to service can be realized by the fact that our service station at Toronto alone cost over $100,000 for equipment that would insure trouble-free operation trucks in that territory. In addition we have service stations in Montreal and Hamilton. The factory at Walkerville has its service department and the different G. & J. dealers have their serivce stations.

"We feel that modern industry requires the motor truck. Thousands of factories find them indispensable. Trucks haul the raw material to factory, and return it finished to the warehouse, from where they haul it to its final destination. They have taken over every function of the horse and wagon, and in addition the functions of the railroad as well. For every haul under two hundred miles motor trucks have proven they can be more profitably employed than railroads. They also effect considerable savings by not requiring goods to be crated."

GARAGE MUST BE ABLE TO HANDLE ANY EMERGENCY

(Continued from page 49)

manufacturer has built his reputation. Just when to begin, however, and when to quit, is sometimes the problem. One house will produce lines that are adaptable to private garage purposes and

Floor and wrecking crane.

even venture into the accessories field with its great field for inventive genius. Another will confine himself to equipment for some specific branch of this rapidly-developing industry.

ONE FIRM INTERESTED

In Calgary there is only one firm interested in automobile work, and they make principally bodies. They sold goods last year to the value of $33.000 and the portion of the plant devoted to this work is valued at $9,000. Thirteen men are employed.

SPECIALIZE ON AUTO PARTS

(Continued from page 41)

last inspection and time of shipment, it is turned back and rectified before leaving the factory. A large percentage of their work is shipped by truck, because the General Motors of Canada, in the same city, use a great amount of their product.

Several well known automobile firms in Canada secure their sheet metal and sheet work from this factory, but although this automotive section is large, it is only a small portion of the entire plant, which we hope to describe in more detail at some future date. Suffice for the present to say, if the part is made of sheet metal or steel, Pedlars can make it, for their equipment is both modern and varied.

DEGREES TO CANADIANS

Among the Canadians who obtained degrees from the Massachusetts Institute of Technology at the recent commencement exercises were the following: Doctor of Philosophy, MacLeod Ewart Hurst, Vancouver, B. C.; Master of Science, Civil Engineering, Walter Maxwell Fine, Edmonton, Alta. Without course classification, Joshua Rowland, Kingham, Victoria, B. C. Bachelor of Science, Mechanical Eng. Irwin Burdette Cassidy, Toronto; Gordon Donaldson Croakery, Kinburn, Ont; Winston Allan Gardiner, Victoria, B. C.; Wilfrid Mulock Thomson, Toronto. Engineering administration, A. G. Oddlafsen, Winnipeg.

Mayor Dawson of Sault Ste. Marie, Ont., together with Ald. James Lyons, president of the Board of Trade, and H. S. Hamilton of Ottawa, recently paid a visit to Ottawa to interview the government in regard to the possibility of securing a rail order for the steel plant to relieve existing unemployment. Commenting on their visit the Mayor stated that, "We interviewed Hon. W. C. Kennedy, Minister of Railways and Canals, and Hon. James Murdock, Minister of Labor, and were told that the government policy in regard to any orders which might be given to relieve unemployment was to be given in the winter, when work was harder to obtain than in the summer. We were assured, however, that the Sault would be given equal treatment with the Sydney mill."

The Matachewan Power Co. are pushing construction work on their power plant now being built on the Montreal River. All the heavy machinery has been ordered and it is expected that this will be delivered to the site this summer. While primarily intended for supplying power to the Matachewan district it is expected that sufficient surplus will be available for distribution to outlying districts, including Gowganda and Shining Tree.

Geo. D. McDougall, chief engineer of The British Empire Steel Corporation, has been elected president of the Nova Scotia Mining Society.

Cutting Costs With Power Riveting Hammers

Work Produced at Great Speed and More Neatly Performed Than By Hand—Controlling the Force of the Blow—Riveting Irregular and Peculiar Shapes

By FRED. R. DANIELS

SEVERAL examples of cold-heating and rivet-setting operations performed on high-speed riveting hammers made by the High Speed Hammer Co., Inc., Rochester, N. Y., are illustrated in this article. One of the reasons that a high-speed riveting hammer is a valuable cost-reducing factor in metal-working plants is that the machine is easy to operate and regulate, so that boys and women are able to turn out as satisfactory a product as the more skilled machinist. The riveting hammer referred to consists of three main units—a pedestal, an attached hammer-head, and an adjustable anvil support. The hammer head carries a friction drive on one side and a pulley that revolves the spindle of the machine on the other, both being mounted on the crankshaft that actuates the hammer movement of the heading tool. The shock of the blows delivered is absorbed by the use of a hickory helve and large rubber bumpers.

The principle of hand riveting is incorporated in this machine in that the cold metal is caused to flow under repeated blows. The force required in delivering these blows for different classes of work is under the control of the operator through the friction clutch and foot-treadle by means of which the machine is operated.

The applications of the riveting hammer mentioned in the following are only examples of the wide field in which this type of hammer is in common use. For delicate work required in typewriter construction and in the manufacture of camera parts and electrical apparatus the high-speed hammer is regularly used. When parts are riveted with a hinge joint and freedom of movement is the prime requisite, the possibility of controlling the force of the blows permits rivets to be set without closing the hinge and causing the leaves to bind.

When rivets are pressed into place before riveting, two operators may be employed for the assembling and the riveting operations, one to press or hammer in the rivets and the other to do the riveting. Often the rivets are not a press fit, but may be assembled by hand in the parts to be riveted, and the work thus assembled passed to the riveter. In this case a boy can do the assembling work and keep the riveting machine in constant operation.

Riveting Rear Axle Drive Shaft Caps

The work being done in the set-up shown in Fig. 1 is the cold-riveting of forged steel hub caps to high-carbon steel rear axle drive shafts, 1¼ inches in diameter. The nature of the work performed in this operation is indicated at A in Fig. 3, from which it will be seen that the shaft extends 3/16 inch beyond the end of the cap, this metal being cold-riveted into the countersunk hole in the cap. This is an example of heavy cold-riveting, the work being done in the plant of the Reo Motor Car Co., Lansing, Mich. For work of this kind it will be readily understood that the peen must be properly shaped to fit the curvature of the cap so that as the tool revolves the rapid elastic blows will set the end of the shaft down even with the

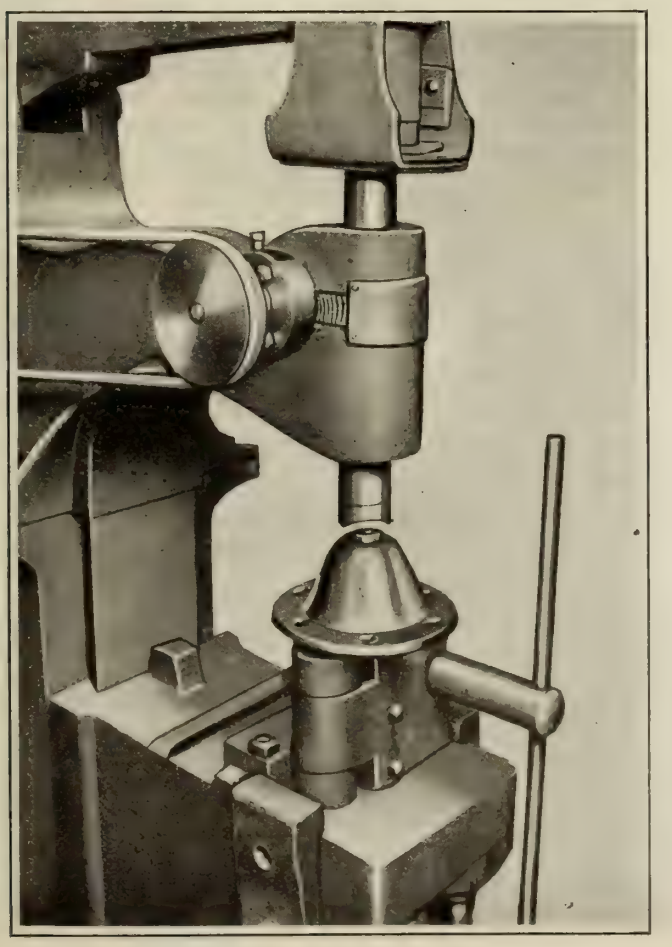

Fig. 1.—Cold riveting of forged steel hub caps to axle shafts.

Fig. 2.—Riveting eight heat-treated steel studs.

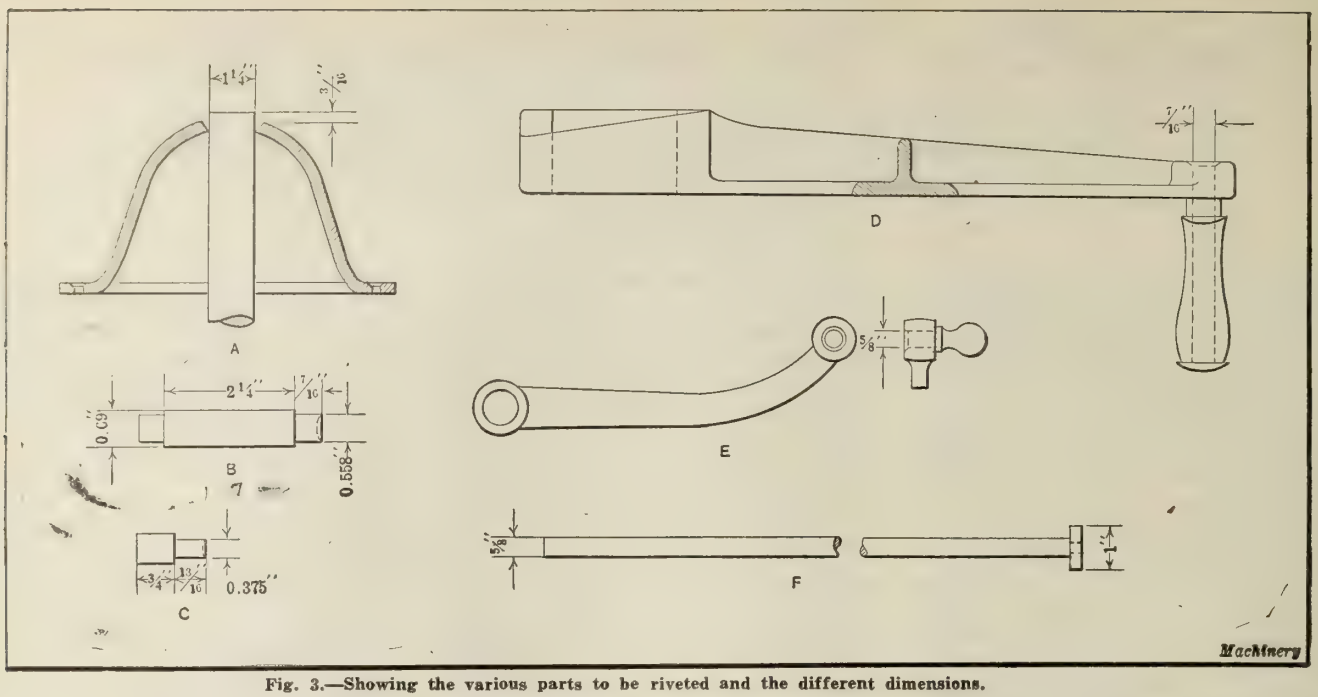

Fig. 3.—Showing the various parts to be riveted and the different dimensions.

curvature of the cap. The work is seated on a special fixture and chucked from within by simply turning the lever-handle a part revolution. The work was formerly done by hand, by which method neither uniformity of product nor speed were realized. Using the sledge hammer the production time was four minutes per shaft; with the machine and set-up illustrated, the time is one minute per shaft.

Operations on Differential Gear-cases

Another manufacturing operation in the automotive industry is illustrated in Fig. 2; this is the riveting of eight heat-treated steel studs in automobile differential gear-cases. This also is a heavy riveting job. The work, which is performed in the New Process Gear Corporation's plant, Syracuse, N. Y., consists first of loosely assembling the side plates, pinions, and studs. These studs are 0.558 inch in diameter on the end to be riveted, as shown at B, Fig. 3. With the gears and studs loosely assembled in the plates, the work is placed on a fixture and a locking pin inserted through the central hole to align the gears while the first stud is riveted. After the first stud is set, the locking pin is withdrawn and the differential gear-case turned around to rivet a second stud located diametrically opposite the first stud.

The operation continues from side to side in pairs until eight rivets have been headed over on the upper side of the case; then the work is reversed and the sequence repeated on the opposite side. During the riveting operation the gears are constantly manipulated by the riveter to detect any tendency for them to bind. The production for one man is from eight to ten completely assembled gear-cases per hour or an average of 144 headed studs.

Application to Wire Wheel Manufacture

Many of these hammers are in use in the manufacture of automobile wire wheels in which their most common application is for riveting the six steel pins in the hub flanges. In one shop this job is handled by two men, one driving the pins into the flanges, and the other setting the rivets. In this way a satisfactory production rate can be obtained.

In another shop, the work is performed by one workman, the operation consisting of cold-heating six steel pins such as shown at C, Fig. 3. It will be seen that the end to be riveted is ⅜ inch in diameter. A fixture plate may be used to hold the rivets in the hub flange in the correct position for riveting after they have been pressed into the holes. The pins are set flush with the face of the flange which, of course, requires a straight-end peen. The production with one man working alone, is 75 hubs per hour, not including the assembling of pins, or 450 pins headed in one hour.

Riveting Crank-handles and Levers

At D, Fig. 3, is shown an engine starting crank on which the riveting operation is the setting over of the pin that passes through the wood handle. These steel pins are 7/16 in in diameter, and some time is consumed in assembling them in the handles. The riveting operation is slowed up, because of the fact that more attention must be given to holding the overhanging end of the crank up at right angles to the face of the peen. The production is 75 cranks an hour.

The riveting of a nickel steel ballend into a forged steel pitman arm for an automobile steering gear requires the use of a large size hammer. The hammer used for this purpose in one plant is equipped with a special anvil in which the ball-end fits while the head is being set. A diagrammatic view of the assembly of a ball-end and pitman arm of the type referred to is shown at E. The diameter of the shank to be riveted, is ⅝ inch and it is pressed into the arm on an arbor press, leaving about ⅛ inch projection to form the rivet head. The head is rounded to ¾ inch

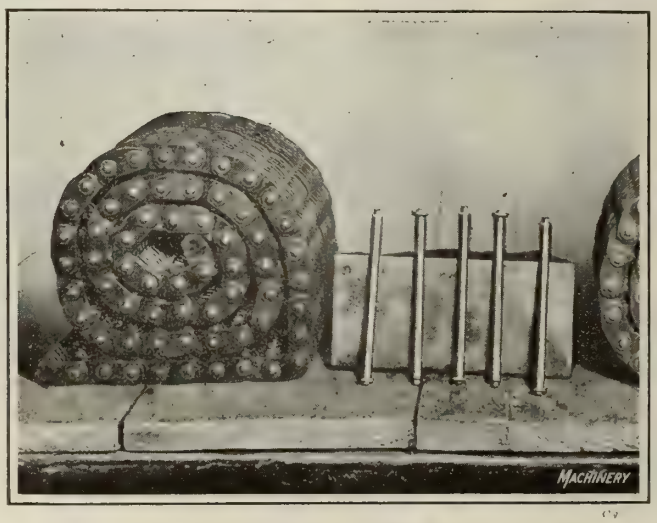

Fig. 5.—Coil of chain and pins on which links are assembled.

diameter, using an oval-head peen, at the rate of 440 per hour.

The setting of a cold-rolled steel head 1 inch in diameter on the end of a 5/16 inch drill rod is a good example of machine riveting. This unit, which is shown at F, forms a driver used in the construction of nailing machines for box manufacture. It will be noticed that the drill rods are comparatively long and slender, and they must be firmly clamped on end during the riveting operation. The type of vise used for this purpose encloses the rod and is split longitudinally, being readily tightened on the rod by a hand lever.

Riveting Brake Brands

The brake-band shown at the right in Fig. 4 is made of steel ¼ inch thick, and is 18 inches in diameter. It is covered with a brake lining which is assembled to it by copper rivets, this being a hand operation. The brackets that hold the lever-and-link device have a foot ¼ inch thick through which the brackets are riveted to the steel band. The illustration shows the position of these brackets after assembling. Steel rivets ¼ inch in diameter are used, sixteen of these being required to assemble both brackets. The production is 304 headed rivets or 19 brake-bands per hour.

Power Riveting in Chain Manufacture

Riveting the ends of pins on which the steel links of silent chains are assembled is regularly performed on the high-speed riveting hammer. The pins used in the particular size of chain illustrated in Fig. 5 are 9/32 inch in diameter, and the width of the chain is 4 inches. The riveted head is set over a washer and the operation must, of course, be so performed that freedom of movement is obtained between the links and spacers of the chain. The average production on this kind of riveting is 600 pins per hour.

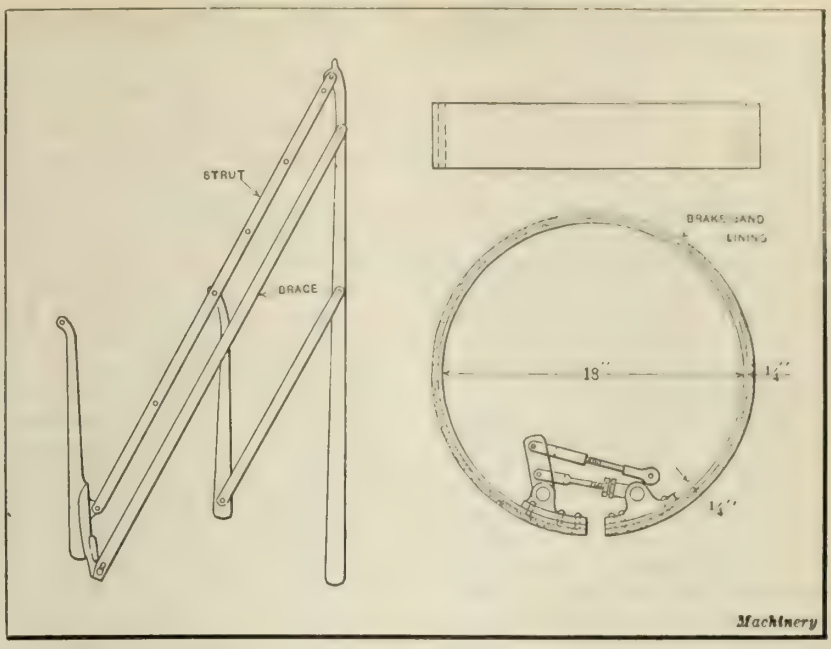

Fig. 4.—Side frame of an automobile top and friction brake-band.

The braces, posts, structs, etc, which go into the side frame of automobile tops are assembled by riveting, and practically all this work is done on power-driven machines. One example of this type is shown in Fig. 6 which illustrates the operation of riveting malleable iron forged clips to a frame post. This post goes into the frame of a Chevrolet automobile top, the work being performed in the American Forging & Socket Co.'s plant at Pontiac, Mich.

The post is made of sheet steel with beaded joint, and is prevented from collapsing during the riveting operation by inserting a mandrel by which one end of the work is held, while the post rests on the specially formed anvil. Two flat-head rivets, 7/32 inch in diameter by 7/16 inch long are used to assemble these clips, the rivets being inserted in place by a boy or woman who then hands them to the riveter to be set down. In operations of this kind when it is necessary to handle the work in this way, a production of 2,000 pieces in a nine-hour day is considered very satisfactory.

At the left in Fig. 4 is shown the assembly of the side frame for an automobile top. The operation to which attention is here directed is setting the seven long rivets in the strut and the short one in the lower end of the brace. Rivets of different lengths are headed without changing the dies. This is accomplished by the use of two anvils which are operated to bring them into alignment with the peen by a foot-treadle. Two of these side-frame assemblies constitute a set, and the production is 250 sets per nine-hour day, or a total of 4,000 rivets daily. This operation shows the possibilities of riveting work of an irregular or peculiar shape by the use of special mechanical devices and fixtures for holding the work.

Fig. 6.—Assembling auto top frames with power riveter.

Power Riveting on Agricultural Implements

The riveting hammer is a common machine in the agricultural machinery plant. It is used in the making of malleable iron chains, shoe runners, mowing machine pitmans, and various other parts. In the plant of Henry & Allen, Auburn, N. Y., malleable iron ends are riveted to a mowing machine pitman arm using eight ¼-inch rivets, four in each side. The heads are set at the rate of 400 per hour, 50 pitmans being completed every six minutes.

Small Gap Lathe Best Suited for Garage

Most Desirable Tool For Range of Work—Various Attachments Make the Machine Almost Universal in Scope—Extension Bid Provides Means of Handling Long Work

GARAGES and service stations are to the automobile owner as doctors and drug stores are to the public—an ever-present need in time of trouble. It is the desire of few to keep them on the regular visiting list but none refrain from calling them in when the necessity arises.

The primary object of the garage is to make speedy and efficient repairs to any and all makes of cars or trucks that may be in service. The ever increasing number of pleasure cars and the rapid expansion in the use of commercial trucks and tractors, necessitate adequate repair shop facilities in all cities, towns, and even in the rural districts. Not alone in the work of repairing automotive equipment, but in the handling of many small jobs of machine repair, can the garage man find an outlet for his service.

Selection of Machines

In the successful operation of a garage the selection of machine equipment is a very important factor. Many small service stations may get along without any machine tools, taking care of all general repairs by getting machine work done in local machine shops. The up-to-date man, however, will obtain the necessary tools for his own service. If it is a question of purchasing one tool, and only one, the choice would naturally be a lathe of suitable dimensions and on which could be used a variety of attachments for taking care of the wide range of operations that would be required in general repair work.

Extension Gap Lathe

For the proper repairing of automobile engines, trucks, tractors and parts, careful attention should be given to the selection of a lathe having the necessary swing, accuracy and equipment conveniences to take care of all of the many jobs—smallest to largest—both in diameter and length. Probably the best all-round purpose machine to meet these conditions would be the sliding extension bed type of gap lathe. The advantages and economy of this type of lathe for general light repair work will be readily seen and appreciated from the accompanying illustrations. The garage is seldom called upon to produce a volume of work but rather a variety so that the sliding extension gap is equivalent to two lathes in one, and likewise is a great saving in cost and floor space occupied.

The lathe on which the different operations here shown are being performed is one that swings 14½in. over the top bed and 24in. diameter through the gap. On the 7½ft. machine the gap opens 36in., and when open will take in lengths of 8 ft. between centres. The carriage travels up to the end of the bed, so that the gap need only be opened wide enough to clear the work. This is very convenient when machining a crank shaft with fly-wheel attached, etc. With the added equipment of taper attachment, milling attachment, and cylinder re-boring device, the lathe becomes a universal machine.

Milling Attachment

A view of the milling attachment is shown in Fig. 1, cutting a key-seat for a Woodruff key. It will be noted that the device is adjustable to almost any desired position, the swivel portion being graduated in degrees. By changing the tools held in the revolving spindle of the lathe, and altering the position of the device many interesting jobs can be accomplished, such as squaring the ends of shafts, sawing bars and heads of screws, splitting bushes, drilling and boring, etc. The advantages of a milling attachment on a garage or repair shop lathe is that it provides a method of doing work that would otherwise have to be sent out to another shop or perhaps filed or accomplished in some ingenious but nevertheless inconvenient and time-consuming manner—expensive to the customer. Hand work takes too much time and rarely is as satisfactory as good machine work. A thoughtful patron will understand and appreciate the difference. When equipped with the milling attachment, as here shown, the extension gap lathe possesses most of the essential features of the milling machinery and the latter is too expensive for the average small garage.

Re-boring Cylinders

A special attachment has been designed for this particular gap lathe whereby the reboring of any make of auto-engine cylinder can be successfully performed, as well as a wide range of general machining of a similar character. The attachment consists of a large angle bracket, the base of which is fastened to the carriage of the lathe. The boring bar is 2½in. dia. and fitted with a Morse taper shank and draw bolt for positive drive. The pilot end of the bar runs in a hardened steel bushing fitted in the body of the angle plate. When placing the work in position, alignment of the bore is facilitated by the use of taper bushings inserted in the cylinder. An angle shoe, that slides on the lower ways of the lathe, takes the weight of the overhanging cylinder body, through two adjusting steady bolts. The power feed of the carriage feeds the work forward and when the cutter has passed through the cylinder it may be removed through the openings in the back of the angle plate, thus leaving a perfect finish on the walls of the cylinder. When the cutter is properly ground a very smooth accurate job can be accomplished. A feature of these gap lathes is their portable nature; the driving motor is attached to a bracket at the front end, while the countershaft is located at the rear of the

Figs. 1 to 4 through courtesy of the Barnes Drill Co., Rockford, Ill. Fig. 5 supplied by South Bend Lathe Works, South Bend, Ind.

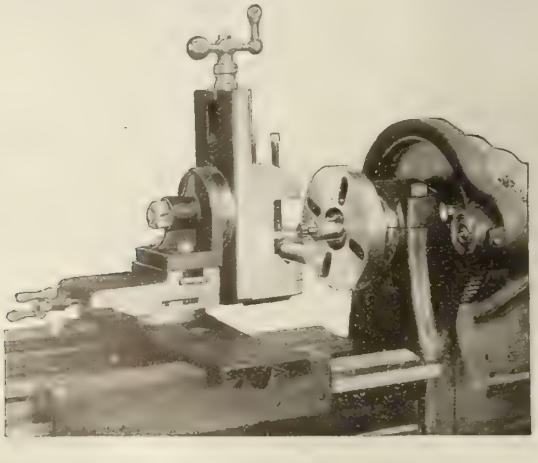

Fig. 1.—Cutting key-seat for Woodruff key.

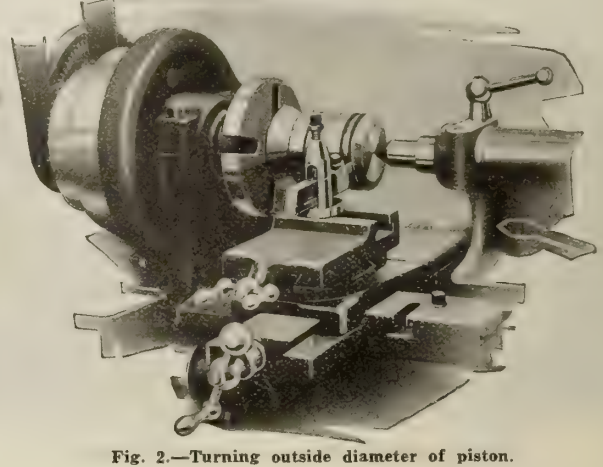

Fig. 2.—Turning outside diameter of piston.

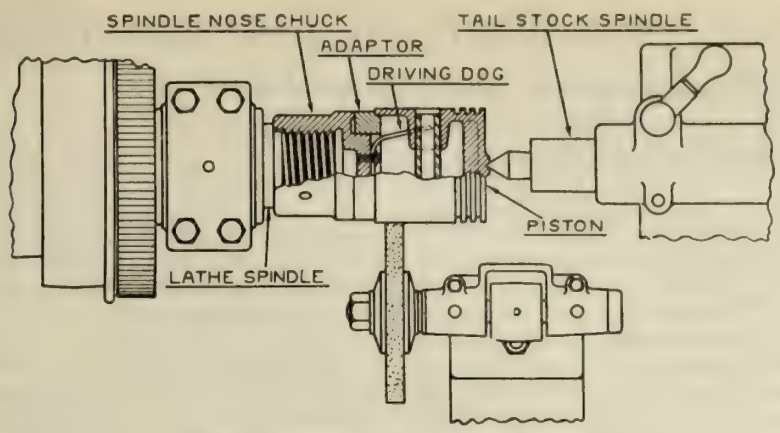

Fig. 5.—Grinding piston on special arbor.

headstock, the cones being belt connected.

Handling Pistons

For the machining of pistons special facilities are provided. In Fig. 2 is shown a piston being turned on the outer diameter. The drive is obtained by means of a combined cone centre and driving plug. The arbor which may be made to fit any spindle is threaded on the centre section, and by means of an adjusting nut back of the cone centre, the latter can be located in the exact position for effective drive, which is accomplished by means of a pin passing through the wrist pin holes of the cylinder and a flat piece inserted in the front end of the arbor.

Another method of driving pistons while the outer diameter is being ground is shown in Fig. 5. A special adapter is made to fit the nose of the lathe spindle and the outside face is turned to take a number of rings, the hole of which fits the nose of the adapter while the outer diameter of the rings are stepped to take the different sized pistons; the driving dog is made of a piece of light bar iron bolted to face of nose chuck and bearing against wrist-pin boss. The outer end of piston runs in the tail centre.

Another attachment is that devised for holding the pistons while boring the wrist pin holes. This appliance has a base for bolting to the face plate, and on the front is a slide that carries a special angle plate on which the work is supported. By means of adjusting screws the position of the work can be regulated independent of the movement of the base on the face plate. The piston is held by means of a V-shaped clamp and bolted with a large flange.

A view that illustrates clearly the range of the machine for large diameters is shown in Fig. 3. Here is shown a fly-wheel held in a chuck while being machined. The movable bed has been drawn back just sufficient to clear the wheel, to retain the maximum support to the lathe carriage. Fig. 4 shows the machine operating on a four-throw crank shaft.

In addition to the above mentioned attachments many others can be devised for facilitating the handling of a wide variety of job work.

MAKE SPECIALTY OF SPRINGS

The Ideal Fence and Spring Co. of Canada, Windsor, Ont., make various kinds of springs for the automobile trade. Here is what W. McGregor, president of the above mentioned firm, has to say regarding their activities. "We have a three story fireproof building, 60 ft. by 140 ft., devoted to the manufacture of springs, cushion seats, etc., most of which is for the automobile trade. Floor space is about 25,00 square feet. The total number of employees at this season, in this part of our factory, is about one hundred, which is normal for about six months of the year. The other six months it drops to about fifty."

MAPLE LEAF TRUCK PLANT IN MONTREAL

THE Maple Leaf Manufacturing Co. was organized in 1919, when the company bought out the Menard Motor Truck Co., of Windsor, Ont. The location of the plant was then moved to Montreal, where active operations were commenced in the spring of 1920. The company at present is engaged in the making of motor trucks ranging from 1½ to 5 ton capacity. The factory is located at 999 Christopher Columbus St. and adjoining the main line of the C. P. R. The building is of frame construction, 100ft. by 125ft.

Since the incorporation of the company, business has shown great expansion and Maple Leaf trucks are operating in all the large cities from Halifax to Vancouver. Demand for trucks has fallen off lately owing to general industrial depression, and to the fact that the Provincial Government of Quebec has recently passed legislation barring the heavier trucks from the roads in the province. It is stated that this ruling seriously affects the business of the company, and the explanation offered by truck manufacturers is that the trucks are overloaded, and as the tires are constructed for pressure per sq. in., the additional weight is destructive to the roadway.

The imported parts used in the car are the Hinckley Motor, the transmissions, front and rear axles, and the steering gear. Included in the parts purchased in Canada are the wheels, tires, bodies and cabs. The chassis are made in the Montreal factory, commercial channel structural steel is used. The plant equipment is ample for assembly, repairs and general service work.

The officers of the company are, Kenneth Molson, president, W. B. McLean, vice-president and general manager, W. F. B. Henry, secty.-treas., and Leslie W. Pearson, sales manager.

Nine hundred men are employed at the plant of the Port Arthur shipbuilding company, the majority being engaged in the construction of the steel freighter Mathewston. The ends are now being built up and the tank tops are nearing completion.

Birmingham Motors Open Plant in Peterborough

Thirty-Five Cars a Day to Be Produced—Unique Suspension of Front and Rear Axles—Flexibility of Car Demonstrated at Recent Exhibition—All Canadian Company

EVER-increasing demand for high grade automobiles has recently brought to Canada another classic car manufacturing concern. This new company is known as Birmingham Motors, Ltd., and early this year they acquired a factory in Peterborough with approximately 11½ acres of land. The present plant is a one-storey building 183 x 187 feet, giving a floor space of over 34,000 sq. ft.

The present value of plant and equipment is about $110,000 and it is estimated that an output of thirty-five cars a day will be obtained under intensive production. The schedule for the first year is placed at two thousand cars of the 124in. wheelbase type. In the construction of the car the company figures on using 80 per cent. of Canadian materials.

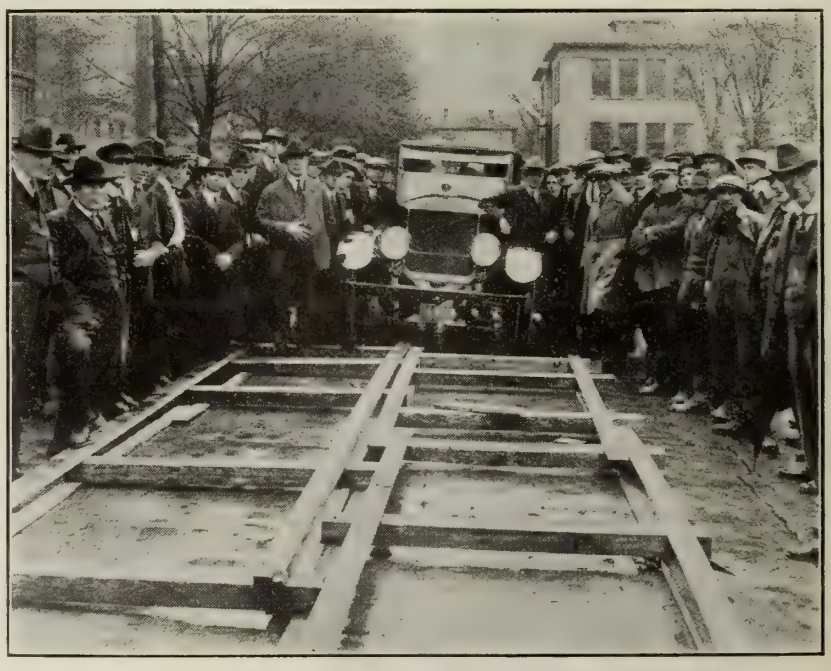
The initial effort of the company will be the assembly of cars, incorporating the most modern and efficient conventional practice. The cars will be equipped with Red Seal Continental six motors, fitted with Stromberg carburetors Bijur starting and lighting equipment, and Gemmer steering gear. The differentials are manufactured by the New Process Gear Corporation, and the transmission is built by the Detroit Gear and Machine Co. As is usual in many types of European cars the bodies will be made of wood supported on a specially designed Parrish frame.

An outstanding feature of the Birmingham car is the unique suspension provided in both front and rear axle. The design of the axles is such that, when under full load, the tie rods and springs are approximately horizontal with the road. The centre bracket of the front axle is rigidly secured to a strong frame receiving member. The tie rods oscillate on the spring coupling pins at the king pin yokes and on the pins at the centre bracket so that the wheels retain their initial position at all times, with a slight increase in tread under load. Oilless bushings are used throughout and leaf springs are made of silicon manganese steel.

The same principle of design is used in the rear axle with the addition of the driving gear. Three leaf springs are used, one above and two below. The inner ends of the tie rods are pinned to the differential housing which is securely fastened to the non-flexing frame. On either side of the housing are located the external contracting service brakes, then the universal joints, the open propeller shafts and the outer universals. It is claimed that this type of axle minimizes the sway and shock when passing over pitchholes and elevations, as the jars are not so localized as in cars with rigid axles.

The application of the spring suspension is not new, as it was originally utilized in the construction of the Cornelian car, but owing to inherent faults in the elementary design, the method did not prove practical. However, after the purchase of the patents, by the Birmingham corporation, their engineers experimented and developed the idea to such a stage that it is now claimed that all previous faults have been eliminated, giving to the present design an ease and riding efficiency of high order.

An interesting demonstration of the flexibility of this car was made at the recent Peterborough Motor Show. The car used was the first made-in-Canada Birmingham car and was driven at ten miles an hour and afterwards at thirty miles an hour, over split 1 to 17in. logs alternately and tied together with stringers. The car was equipped with Dunlop cord tires and the test was a severe one, as may be gathered from the accompanying cut, which shows the obstruction passed over at the speeds mentioned.



The Peterborough plant will be owned and operated by the Canadian company and will be under the managership of Byron Tederer. It is stated that, wherever possible, Canadian material will be used for construction. Present activities are devoted to the better class car, selling at approximately $2,600, but the engineers are working on a design of a four-cylinder type, with same suspension, that will sell at about $1,200. It is anticipated that this car will be completed for exhibition at the National Motor Show which will be held in conjunction with the Toronto National Exhibition in September.

RUNNING NIGHT AND DAY

SPEAKING about their tire plant at Oakville, J. B. Maus, director of sales for the Oak Tire & Rubber Co., says:—

"The valuation of our company is $250,000, and the ground covered by the factory and available space, approximately six and a half acres. We employ about 120 men, and at the present time are running both night and day to supply the demand. Our pay roll averages about $100,000 and our production at capacity is approximately one million dollars.

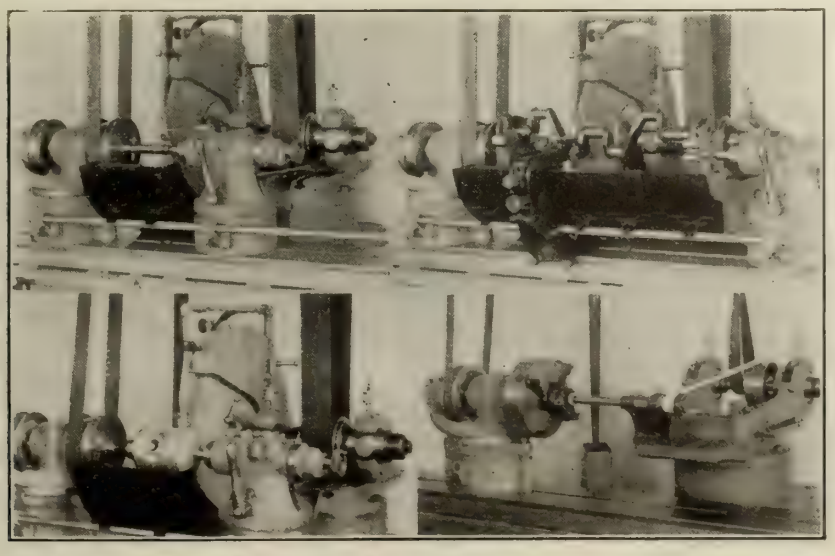
"The rubber and tire industry in Canada is particularly attractive and holds a very promising future for the following reasons:—First, the consumption of cars for the Dominion is about one car to every twenty of its population, while in the United States it is approximately one car to every nine, showing that our consumption of cars in the Dominion is approximately 100 per cent. less per population. It is due first to the undeveloped roads that are rapidly being improved and secondly the past high prices of cars which in recent months have been greatly reduced, and as a result the use of the automobile in the Dominion has become more popular each day, necessitating thereby the additional use of automobile tires.

Test of Birmingham car at Peterboro Motor Show.

Accurate Production Grinding of General Automotive Equipment

MEETING the growing demand for improved grinding equipment for the accurate finishing of automobile parts is a constant problem of the machine tool manufacturers. Some of the principal operations carried out in the grinding of auto parts are shown in the accompanying illustration. The success of crankshaft grinding is mainly dependent on the accurate, careful construction of the throw blocks. Those used on this machine are made with tool-room precision. The sides of the block are finished to an exact size in relation to the centre holes in the sliding blocks, this permitting the crankshaft to be readily aligned by placing the blocks on their sides upon a surface plate. Other features of these blocks are the adjustable clamp caps which provide for various diameters of shafts, the three centre holes for crankshafts of different throws, the adjustable slide for obtaining a firmer setting, and the special extension of the slide block used on the headstock end of the crankshaft. This extension, with its recess, provides for grinding flanged crankshafts.

Another noteworthy feature is the piston arbor. Motor mechanics will appreciate the time saved in mounting pistons in this convenient manner. In addition to the piston being mounted on dead centres, it is likewise ground upon its own centres, which not only assures accuracy, but trues up a seasoned piston concentric with the same axis upon which it was originally turned. Having no three-point bearing to establish, the tendency for the piston to cramp or become off centre is eliminated.



The machine itself is particularly designed for automobile production work and general repairs in large garages.

The wheel spindle of tool steel has hardened bearings, ground and lapped, running in self-aligning phosphor bronze boxes, provided with means of compensation for wear. The spindle and boxes can be easily removed to make room for the internal grinding attachment. The automatic cross feed will move the wheel from .00025in. to .004in. at each reversal of the table, as desired. It is automatically disengaged when the work is to size. The table travel is automatic and is controlled by easily adjustable dogs. The speeds and feeds of the wheel and the work table feed are entirely independent of each other. A single lever starts and stops the rotation of the work and the feed of the table. The table reversing mechanism is very accurate allowing work to be ground close to the shoulder.

The base of the machine rests on the floor at three points. This maintains the alignment of the table, preventing it from being affected by any inaccuracies of the flooring. The box-like construction of the frame with the ample overhang at each end gives firm support for the table, especially at the end of its traverse. Strong ribbing extending the entire length of the table, keeps it rigid and prevents it from sagging. The grinding wheel is 24in. in diameter, 1in. thick, and has a 5in. hole. It is amply protected by a heavy guard which helps to confine the spray and particles of abrasive. The footstock carries the holder for the carbon point and the wheel can be trued without removing the work from the centres.

The machine is equipped with a small pump for supplying water to the wheel when doing wet grinding.

Announcement has been made of the appointment of R. A. Parrish to the position of general organizer and publicity agent of the Edmonton Automobile and Good Road Association.

BRIEF REVIEW OF ACTIVITIES AT WILLYS-OVERLAND

ON January 8, 1920, we published a twelve page article entitled, "Making the Overland Four." At that time we described the factory in detail, and explained the different operations on the car. It is unnecessary to repeat the information then given, we will therefore in this article, give a brief review on the method of manufacture.

There is the assembling of chassis, the painting department, further stages of assembly, etc. Each operation is carefully inspected, and not only are the engines made at their plant, but all machining operations on front axle are completed at the main factory.

The rear axle and transmission are made at another factory, but Canadian labor is employed. In the making of the various parts, only high class equipment is used, and jigs and fixtures have been developed to a fine point. Here are a few samples.

The chassis is assembled on a specially constructed frame, the front axle is milled on a special machine and this piece is drilled on a four-spindle adjustable head drill press, a locating jig being used. The cylinder blocks are also machined on jigs, and a specially constructed eight-spindle boring mill bores out the blocks at one time. A circular table allows the operator to load and unload while the machine spindles are performing their work.

Special multiple spindle machines are used to drill the tops and bottoms of cylinder blocks and in one case a horizontal machine is used which drills 47 holes at one time. Another tool machine mills the connecting rods, on a continuous milling table, in fact, as mentioned previously, all the equipment is of the very latest type. In every case, close inspection is adhered to, and the reader's best plan would be to secure a copy of the original material and read the complete story.

Since writing our last article on January 8, 1920, several changes to the executive have occurred but the old reliable T. A. Russell is still at the helm. Following is a brief history of Mr. Russell's activities, also a short story covering two other members of the executive.

Mr. T. A. Russell is president and after being graduated from Toronto University, was secretary of the Canadian Manufacturers' Association. His organizing ability led to his selection by the Canada Cycle and Motor Co. and for a number of years he successfully directed its activities. Later on, he organized the Russell Motor Car Co. which manufactured the Russell-Knight motor car until affiliation was made with the Willys-Overland interest of the United States. Under the arrangement by which the Canadian Willys-Overland Co. undertook the manufacture of cars in Canada, the Russell factories were taken over, and Willys-Overland Ltd., now has ramifications all through Canada with its own

(Continued on page 58)

Yearly Production Averages Around Quarter of a Million

THE FOUR Wheel Drive Auto Co. at Kitchener, Ont., have a plant, with about seven acres of land, worth over $50,000. Speaking about their activities, A. M. Kerr, manager of the plant, says: "Our number of employees varies according to seasons from five, up to any number. Our yearly production averages about a quarter million dollars. We, of course, have just started in Canada, and started at a very bad time, but we expect our yearly production to rapidly increase. In time we expect to take care of a considerable amount of foreign trade. That will be made possible by the workings of our preferential tariff. Another factor which we expect will give us a great deal of business is the recent development of our railroad truck.

"This truck is our standard article with the rubber tires taken off and steel flanged wheels put on in their places. Our truck is built with a standard 56½" tread, so that no changes are necessary from an engineering standpoint to adapt it to the rails, which are 56½" gauge. We also have traction on the front wheels as well as on the rear which allows the front end to do as much as the rear end, giving a pulling capacity and traction effort which no other rear driven truck can obtain. That is going to mean a lot of business for railways operating short lines and unproductive lines with steam trains. The cost of our equipment is only a fraction of the cost of steam equipment and the operating and upkeep charges are similarly low. As we have specialized on a road building truck and a merchandise truck, for hauling trailers, so we are specializing on this railroad equipment.

"Our main factory in Clintonville builds nothing but one size and model of truck, therefore is it reasonable to suppose that they build a good one. All the changes they make from year to year do not necessitate new models as all changes are interchangeable with all trucks built from the very first.

"Business is getting more active for us, and we hope very soon to get back to normal. We consider our plant well equipped, and chief among the necessary equipment is a heat-treating plant where all steel after it has been passed as being of the proper construction, is subjected to heat at a set temperature for different lengths of time, to give it the toughness and hardness necessary. There is also the process of carbonizing steels, which consists of hardening the surface of the metal to a certain depth leaving the core soft and pliable, thus giving combined flexibility and strength and wearing qualities.

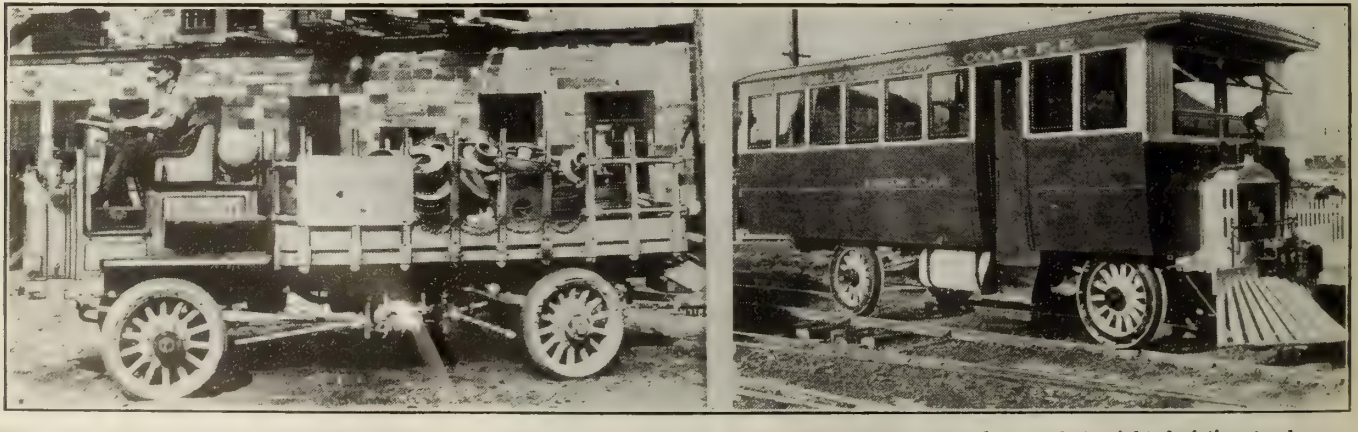
"There is also an important part in our process of manufacture and that is the gauging of all parts and bearings, with the latest type of gauges, which are proved on Swedish blocks to a very minute fraction of an inch. To the ordinary individual this would seem like unnecessary expense, but statistics show that a truck built thus, and costing a little more money than an assembled proposition, lasts a great deal longer and costs considerably less in upkeep charges, especially after the first year or two.

"With our particular truck we feel there is nothing known to motor science that is not practised in our factory. Another feature of our operations is our construction and assembly of the Four Wheel Drive principle. This is so simple, yet so effective. The application of the universal joint principle is applied the same way as that principle is applied universally by all manufacturers of motors, in their transmissions. The ball and socket support for the front axle together with the direct drive through the axle housing is the secret of the successful operation of the drive on all four wheels."

A total of 2,448 automobile licenses were issued by the Province of Manitoba license department up to the end of April this year.

BRIEF REVIEWS

(Continued from Page 57)



branches in Toronto, Montreal, Winnipeg and Regina. Mr. Russell not only has the active-management of Willys-Overland, but is vice-president of the Russell Motor Car Co., president of the Canada Cycle & Motor Co. and president of the Russell Gear & Machine Co., in all of which he takes an active part. He is also a director of the Canadian Bank of Commerce, and of the Canada Cement Co., and in addition to these interests he takes a very personal supervision of his splendid farm at Downsview, the home of some of Canada's best pure-bred Shorthorns.

Mr. John R. Marlow, secretary-treasurer of the company, who is also sales director, has had long experience in the automobile business, having been with Mr. Russell since the early days of his enterprises. Leaving the sales management of the old Russell Motor Car Co. to go to Montreal as branch manager, he remained in that city for a number of years, continuing as branch manager when Willys-Overland took over the Russell Motor Car Co. interests. Early in 1921 he was promoted to the office of secretary-treasurer and at the same time assumed the management of the sales division, in which he has met with marked success.

Mr. Fred G. Adams, factory superintendent, has also been connected with Mr. Russell's business activities since the early bicycle days, and had much to do with carrying out the large shell contracts which the Russell Motor Car Co. worked during the war. When the war work was completed at the Russell Motor plant, Mr. Adams came to the Willys-Overland factories and has been in charge of production since that time.

The area of plant and office buildings is approximately 5½ acres, the total floor space 311,215 sq. ft., the total valuation of plant and office buildings, $2,480,000, while the approximate value of machines and equipment in factory is about $1,620,000.

Old age has its joys but reckless men do not live to enjoy them.

Showing two extreme uses for F.W.D. motor trucks. The left view shows truck used in steel foundry, the photograph to right depicting truck on railway.

Yearly Output Totals 260,000 Automobile Wheels

Also Manufactures Front and Rear Axles—Continuous Operations on Wheel Spokes—Turret Lathes Used in Making Hubs—Every Axle Tested Before Being Shipped

TO FOLLOW the making of an automobile wheel is an interesting study. At the Hayes Wheel Co. of Canada, Chatham, Ont., they turn out enough wheels and material to accommodate 65,000 cars per year. Here we find a specialized industry which has been brought to a high point of efficiency, every operation being in sequence, both in the wood and metal working departments.

Wheels are made for Ford, Maxwell, Briscoe, Chevrolet, Gray Dort, Oldsmobile, McLaughlin, and Willys-Overland cars, also several other makes. At Chatham wooden-spoked, and steel felloe wheels are manufactured while in the other plant, which is in Windsor, the outer steel rim carriers are manufactured.

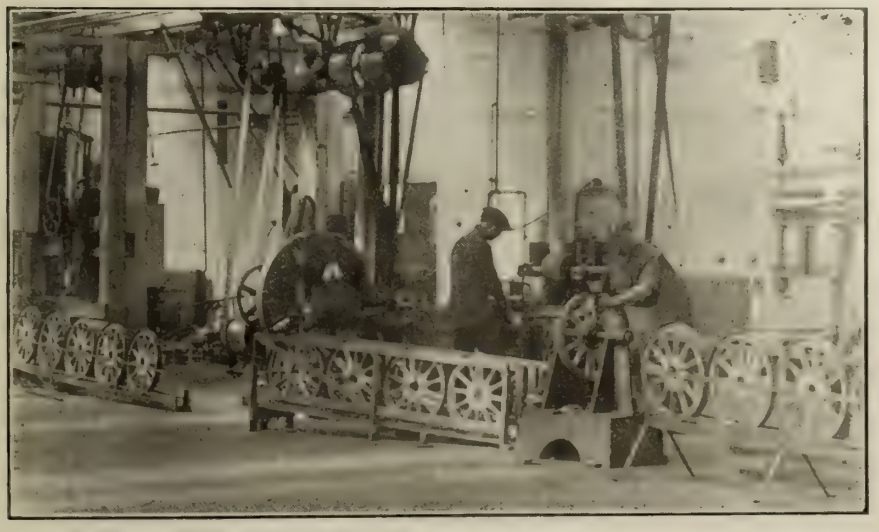
The total value of both plants is $732,000, about $532,000 of this being in the Chatham factory. In Windsor the plant covers 5 acres while in Chatham the property is about 4 acres. A total of 400 are employed, 300 in Chatham and 100 in Windsor. The average monthly pay roll in both plants is $40,000, and the two factories make about $3,000,000 sales each year. Considerable export business is done, this swelling the total.

In addition to wheels, this firm make front and rear axles, also steering gears for several types of cars. Starting with the woodworking section of the wheel plant we find that the spokes are turned on a lathe with remarkable rapidity by means of a large knife, while the end is formed to meet the hub by means of two mitre knives in a machine very much after the style of a punch press. These knives are never stopped, the operator merely slipping a spoke in place, down comes the knives, and the two bevel edges are trimmed.

The moment this is done, the operator tosses the spoke down a chute, where it is lifted up with a belt to a sander which finishes the rough turned spoke. Next they are assembled to the outside rim and the metal hub, being squeezed up into place by an air-driven machine worked on the tire setter principle.

Digressing for a moment to the metal hub, we shall follow the method employed in finishing this part. Everyone is familiar with the appearance of a hub for a wheel, so no sketch is necessary. A series of turret lathes, both single and double spindle, are tooled in step-up operations, the parts progressing along the line until completion. The flange is turned, the hub bored, faced and threaded. These are the principal steps, and standard tooling is used. These hubs are completed in a separate part of the plant so that the two sections, wood and metals, do not conflict.

After the hubs have been assembled to the rim and spokes, the bolts are tightened, and the wheel passed along a chute to be painted. An automatic dipping tub is used for the painting. After this operation the wheels are shipped to whatever factory requires them.



Making The Axle

In making the front axles, it must be understood that the drop forgings are made at an outside plant. The machinery operations are simple yet effective. The axle is drilled in a multiple spindle drill, and held in a jig with floating Vee blocks. The holes for knuckle pin at end, also spring pad holes are drilled at this operation.

On an ordinary milling machine the bosses on the forked ends of axle are milled to width, also the spring pads. The knuckles are machines on turret lathes, and as this merely consists of taper turning and threading we need not dwell at length on the matter. The assembly is practically a duplicate of the methods adopted in the other automobile plants discussed in this issue.

The making of the rear axle is a different proposition, and the gears used in same are not cut in Chatham, but are purchased from an outside firm. The housings are machined on lathes, and after being assembled to the tubular sections, the gears are placed in position with axle and gears, after which every axle is tested for smooth running qualities. In a general article of this nature it is not necessary to dwell on any particular operation, but rather touch on the routine. To give some idea of how much material was purchased from other Canadian firms in the making of these four lines, wheels, front and rear axles, and steering gear, we find that over one million dollars is spent yearly in Canada on miscellaneous metals and parts.

To keep production up in these varied lines, the following personnel lend their executive ability: president, C. B. Hayes; general manager, Wm. Kistler; factory manager, W. A. Wecker; sales manager, V. B. Moorey; purchasing agent, H. W. Taylor; auditor, Wilfred Peck; engineer, J. E. McCauley; supt. axles, Robert Milhiser; supt. wheels, C. Kistler; supt. rims, forgings, R. B. Craig; tool maintenance, Joseph Sullivan, and chief inspector, R. D. Evans.

Making wheels at the Hayes plant.

MAKE AUTOMOBILE BOWS

Merritt & Co., Chatham, Ont., make all sorts of bent shapes, such as automobile bows, etc., for the automobile trade. At present they are exceptionally busy, and following are some particulars regarding their plant:—

Value of plant about $60,000.00, floor space approximately 16,000 sq. ft., number of employees at present, 18, monthly pay roll $1,500.00, yearly production, $115,000.00. About 85 per cent. of their raw material comes from the hardwood regions of the Southern States.

C. H. Merritt is manager and secretary-treasurer, Mr. G. B. Merritt is president, while Mr. Amos Jacklin and James Tedford act as foremen in the factory.

SEVERAL GOOD METHODS OF MILLING SPLINES

The adaptability of the milling machine for the accomplishment of out of the ordinary jobs is shown in the illustration herewith. At the top left is shown a plain milling machine cutting a woodruff keyway in a small shaft. The vice is clamped to the table with the jaws parallel to the ways of the table. The cutter is located directly over the center of the shaft and the work is raised to permit the cutter to enter to the desired depth.

A simple method of cutting a keyway in a shaft is shown in the upper right hand view. The arbor is of the fly type, the cutter being a short lathe tool or bit of high speed tool ground to the width of the keyway required.

At the lower left is illustrated a method of cutting multiple splines. This is an interesting operation and one that would often be met with in motor service. The side cutters are used in pairs, set with micrometers to the desired spacing or key width. The work is mounted in the dividing head chuck with the other end in the tail centre. The table is adjusted so that the centre of the shaft or work comes directly in line with the centre of space between the cutters. Set the dividing head for the proper spline spacing. Raise the work to the desired height and allow the cutters to mill the first spline. Return work to initial position and repeat until milling is completed. The ridge left in the groove between the splines is removed by means of a fly cutter operated as mentioned previously and shown at the top centre.

The use of an end mill or fish tail cutter for the milling of keyways or grooves is illustrated in the lower centre view. Set the swivel vice on machine table and clamp the vice in such a position as will bring the taper of the work parallel with the ways of the table and raise the latter until the shaft centres coincide. The cutting is then performed in the usual way.

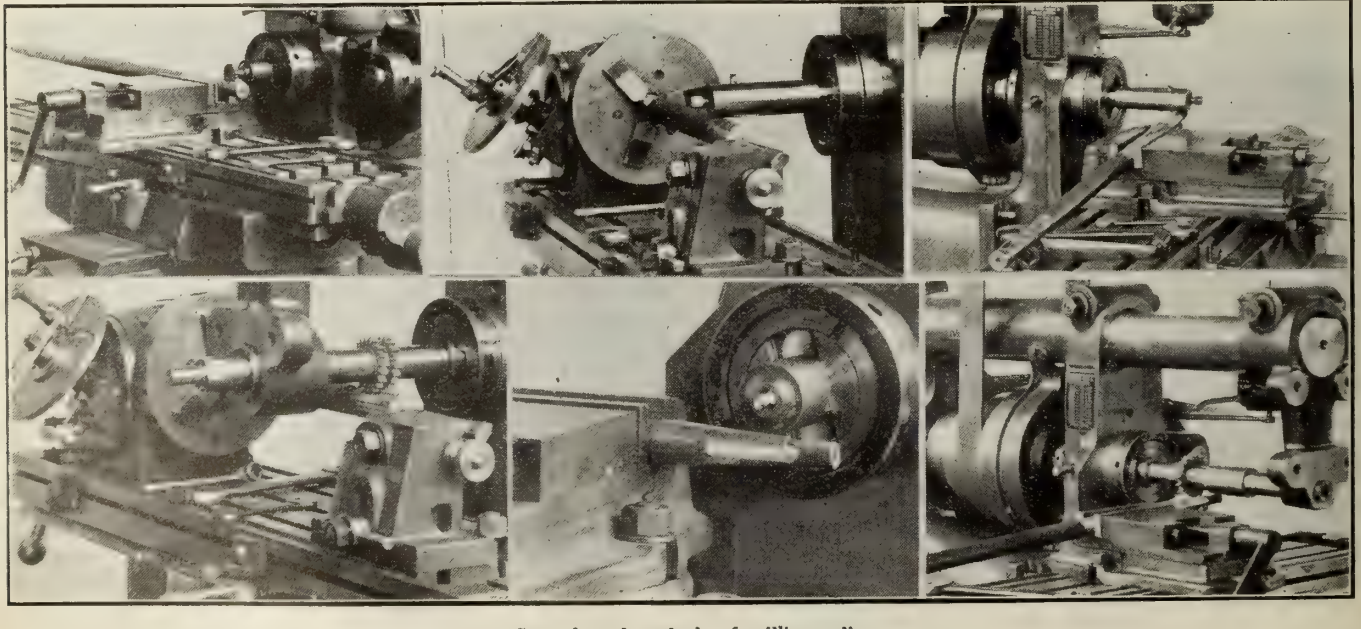
Still another method is shown at the lower right for cutting a keyway with a spline cutter. The arbor in this instance is supported by the pendant giving added rigidity to the cutter and permitting of speeding up production.

MAKES WINDSHIELDS AND OTHER AUTOMOTIVE PARTS, ALSO MIRRORS

AT THE motor Products Corporation, Walkerville, Ont., windshields and other automotive equipment are manufactured. The plant has a floor space of 50,199 sq. ft., and is valued at $400,000. The property owned is ample for future expansion, approximately 17½ acres completing the plant and yard. At present 150 men are employed and the average monthly wage is $25,000.

The principal line of manufacture is windshields and the average person would hardly believe that some 75 parts go into every windshield. Then there are several different models according to the make and type of car, so that to provide for all this, they have to be well equipped. Tubing products, stampings, hub caps, commercial mirrors, clutch disc pads, etc., form part of other lines produced. The glass used in the windshields and mirrors is imported from Belgium and England. This is cut to form at the Walkerville factory, the glass coming in large sheets of suitable size.

The rolling of tubing is particularly interesting. The metal is fed in strips of proper width, passes through a series of rollers, and comes out at the other end completely formed. According to the style of windshield, the form of tubing varies. The rubber weather strips are of Tee shape, fitting firmly into outside frame of shield. The process of rolling the different forms of tubing is identical, the only change being in the shape of rollers used. Running board moulding is also rolled in somewhat similar manner.



In making vision mirrors for automobiles, the small pieces of glass left over from windshields are utilized, being silvered to suit. Adjusting brackets, and other castings and sheet metal parts used on these mirrors are finished and enamelled at the plant. Other tubing parts such as radius rods for Fords, etc., are also produced.

The metal stamping section is well equipped and arranged to handle work very quickly. Steel tool boxes, robe rails, and rear curtain lights, are a few of their other lines. Close inspection is adhered to throughout the plant, and nothing is passed until absolutely correct.

H. J Stoops is general manager of the factory, E. H. Carr, office manager, and W. Thatcher, sales manager.

NEW FACTORY AT WALKERVILLE

The Timken Roller Bearings Co., factory at Walkerville, Ont., was started owing to the growing demand in Canada for this type of bearing, according to statements made by R. E. Mackenzie, of the American plant at Canton, Ohio. He says that the combined floor space of all factories in America, France, England and Canada is more than fifty acres. The Canadian plant is at present only beginning, but it is expected to develop rapidly. Mr. Mackenzie states that Canadian engineers, both in automotive and industrial machinery fields can rest assured of the same constant source of supply in Canada, as in the States or abroad.

Several good methods of milling splines.

65,000 Automobile Bodies A Year

CONTRARY to popular opinion, all automobile bodies are not completed in automotive factories. Body building is a trade in itself, and requires a large investment if reasonable production is to be secured. For this reason, several automobile factories find it much better to order the bodies from a regular body factory. Usually these are delivered in finished condition, but in some cases, the body is sent minus the finish varnish coat. Whatever plan is adopted, the task of building, ready for painting remains the same, and we will describe how the Fisher Body Co., of Canada proceeds with this work.

This firm, which has two plants in Walkerville, Ont., valued at over half a million dollars, builds practically all Ford bodies used in Canada.

In addition, they make bodies for the General Motors and other automobile concerns. As a large percentage of the building of car bodies consists in preparing the wood to size and length, they have a very large woodworking department, for between 60,000 and 75,000 bodies are finished every year. They are at present working up to full capacity, and have around 600 employees. All the lumber used is purchased in Canada, and although about 70 per cent. of the steel is bought in from the States, it is fabricated in Canada.

Wood Working

To enter into detail regarding all the woodworking operations would take a volume, for some of the parts have several operations. Enough to say that everything is shaped to standard forms, these being kept in one department on shelves similar to any pattern storage. Looking at some of the finished, peculiar shaped pieces in a body, you first wonder how they cut them all the same, but the wonder soon vanishes when you see the operation being performed.

The form holding the piece to be cut rides over a steel collar on machine. This is set a predetermined distance from the knife. The operator simply pushes the form over the collar, forgetting entirely the part inside which is being shaped, for he knows it is bound to come right.

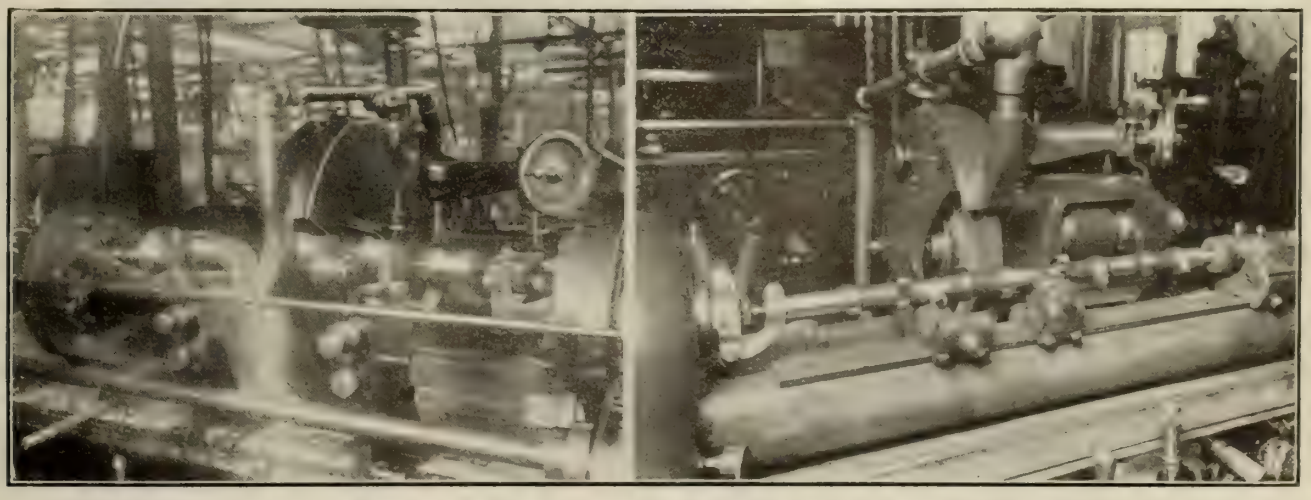
Where the parts are large, two men usually handle the forms, and in many cases they are reversible, especially where right and left hand parts are required. That is, two rough pieces of lumber are placed in the form at one time, one at top, the other at the bottom. Then there are the curved or bent parts. These are first steamed, next bent to form, tacked in place, and set in a dry kiln until seasoned to shape.

The men work in teams when building bodies, and start somewhat after the fashion of a shipbuilder. A master frame stands on the floor, and into this the men assemble the framework piece by piece. Once this is securely fastened together, the frame is covered with the metal, that is, the sheet metal. This being completed, the upholstery is added, and the body leaves the assembly floor ready for painting. During the metalling operation, the doors are hung and other general hardware added. The doors themselves are metalled on separate assembly stands, shaped to suit the curvature of the door. This operation is generally done by one man only, and he completes a door before lifting it off the stand.

Body Painting

While there are other minor operations we have not touched upon, the important one of painting must not be overlooked. They are very proud of their painting methods, and are exceptionally careful to see that a body is absolutely clean before paint of any kind is applied. The slightest particle of grease means that the enamel will not stick to that portion, and everything possible is done to ensure against this trouble.

After cleaning, the usual wood primer is applied, also the metal primer, glaze, and two or three coats of enamel, depending upon the make of the car. The regular rubbing process occurs between each coat in order to make sure all parts are smooth and even. Nail holes, and other depressions which cannot be avoided are putty glazed to proper level before the enamel is applied. After enamelling, the bodies are dried in a large oven.



The upholstery end of the automobile business has been touched upon in another article in this issue, so no comment will be made regarding the procedure here. The making of bodies is a highly specialized business, and a tie-up in even one small section plays havoc with the schedule.

It is this thought of careful planning of operations that impresses a visitor, and The Fisher Co., here studied and mastered this phase of manufacturing. They have had nine years' experience, and in that time have made the most of their opportunities. The result is a well balanced organization, and a staff working like clockwork in the factory. Mr. Henkes is factory manager.

GRINDING CAM AND CRANK SHAFTS

Two interesting grinding operations are illustrated herewith. The view on the left shows a Mitchell crankshaft being ground in a Landis grinder. These shafts are of drop forged steel with a scleroscope hardness of 38 to 48. They are first rough turned to within 0.050 in. of finished size. The finished diameter of the pins is 2 in. with high and low limits of .001 in. The width is finished to 2.25 in. with limits either way of .0025 in. Rough grinding removes about .036 in. and from .012 to .015 in. is removed in the finish grinding operation. The machine operates at a production rate of 25 crankshafts per hour.

The view to the right shows the grinding of forged steel automobile camshafts for 4-cylinder engines. The machine used is a Landis 10 in. by 36 in. fitted with underslung cam attachment. In the roughing operation 1/16 in. of stock is removed and .010 in. is ground off in the finishing cut. The time for roughing is 8 minutes on the complete shaft and the finishing is completed in a like period of time.

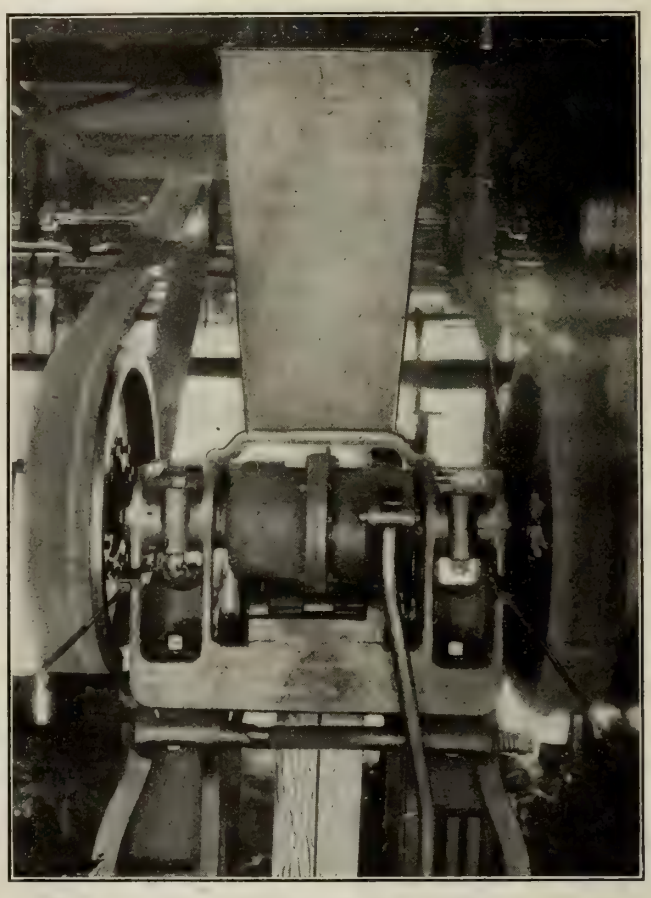
Left.—Grinding Mitchell crankshaft on Landis Grinder. Right—Grinding forged steel automobile camshaft.

Safety and Production Go Hand in Hand

Mechanical Guards Provide Adequate Protection From Flying Particles of Hot Metal—Output Increased As Result of Safety Methods—Low Cost of Handling Material

IN A plant valued at $1,500,000 the Dominion Forge & Stamping Co., Walkerville, Ontario, supply to a considerable extent the Canadian automobile and allied industries with their necessary drop forgings. This plant covers nine acres and employs 200 at the present time. This is on a single shift, but during the war days as high as 450 have been employed.

The equipment in a large drop forging plant is always impressive and when you enter this factory you cannot help but realize that everyone is working with a will. When their 8,000 pound steam hammers and 3,000 pound board drop hammers get to work it is no time for pleasant conversation and the only thing you can do is to look around and make notes. When looking around however you are in no danger of being blinded by the flying particles of hot metal. Every man in this plant wears goggles and so do visitors when shown through the shops. This plant is trying to be 100 per cent. safe. The story of how goggles came to be worn generally is told on page 36 of the Canadian Machinery, May 4th issue.



The company has systematically installed guards on every machine that it is possible to guard. A survey was made of the entire plant and every machine studied for the purpose of making it as safe as mechanical guards could make it. After the survey had been made the machines were all guarded. Board hammers were equipped with funnel-shaped boxes to catch broken boards, treadles are covered and each hammer has a suitable block for blocking the ram. Steam hammers have every known guard on them and the cold trim presses are all operated by electric tripping devices. The handling of material has been made safe by a careful study of the routine of raw and finished material and the elimination of unnecessary handling. A system of handling which combines steel boxes, barrels, crates and bins with electric trucks and hydraulic elevators, has not only reduced the number of injuries but cut the cost of handling material to a very low figure.

Not only has this company spent money in the plant to prevent injuries but it has gone outside of the plant to protect the men. Near the plant is a dangerous railway crossing. "Near accidents" were of almost daily occurrence, so the company asked the railway people to install a crossing bell. After considerable correspondence and a final refusal by the railway to provide the protection the company paid for the installation of an alarm bell. In explanation of this action the company says, "would it not be foolish to provide guards in the plant to protect the men and then fail to protect them a few hundred feet from the front door because a protective device costs $800?"

Not only has the company spent $25,000 in the past two years for installing mechanical guards in the shop and at the crossing near the plant but it has taken an active part in the public safety campaign conducted in the Border Cities.

Discipline and strict enforcement of shop safety rules play a big part in plant. The men have become convinced that the company is sincere in its efforts to prevent accidents and cooperate nicely. How important a part in the daily shop life "safety" has attained is shown in the following story: A workman reported to the safety department that a certain oiler, although he had been warned several times, persisted in oiling machinery and line shaft while in motion. The oiler was called into the safety office and asked if he had read the "safety" rules. He said he had and he was then told that apparently they did not mean much to him and that he had better read them out loud. He was given a rule book and told to read the first page out loud; "WORK SAFELY. This is your first duty to yourself, your family and your employer. There is a safe way to do every job; learn it and do it that way. Start Now." He was then told to look up rule twelve and read that out loud. Rule 12 is as follows: Cleaning and oiling machinery when in motion is prohibited.

After having read these rules he was told that further infraction might result in one of two things; that he might be instantly killed or discharged and that the manager preferred to discharge him. He was also told that he should heed the warnings and advice from the men working near him. The lesson given him that day had a lasting effect and he became enthusiastic regarding safety in his work.

Board lift drop press with protecting guard above.

The natural question, after seeing all the evidences of money having been spent is: Has all this expenditure really reduced accidents?

The answer to that question was very simple, yet effective. Four file drawers were drawn out, one each for 1918,

(Continued on page 63)

Making Springs For Various Cars

MAKING springs for automobiles is a special industry in itself. The automotive manufacturer does not care to tie up a large amount of capital in a spring plant, when he can procure all necessary springs from a factory already in operation. This practice is carried out by practically every car manufacturer, and the majority of Canadian requirements are filled at the Dowsley Spring & Axle Co., Chatham, Ont.

This plant has a total floor space of 60,000 sq. ft., and employes 140. The average monthly pay roll is about $14,000, and the yearly production would total $875,000. The ground owned covers 10 acres, so there is ample of room for expansion. About 4,000 to 5,000 tons of material is used every year, and springs are made for Gray Dort, Ford, Studebaker, Willys-Overland, and Chalmers cars. The process of manufacture sounds simple, but patient experimenting was practised before the present method was finally adopted.

Starting from the store room we have the raw stock. This is brought into one building and sheared to proper length, after which the parts are diamond trimmed, and points ground and beveled.

The eye on the large leaf is now formed, then the leafs pass to another building for heat treatment. In heat treatment, the leafs are placed in forming fires, heated to proper temperature, then on a forming jack over a tank of water. Each plate is fitted at this stage to the individual leaf of spring it has to be assembled to. In order to avoid confusion, the leafs are marked in some manner such as: 0, or 00, as the case may be. This means they would be marked, 01, 02, 03, etc., depending upon the number in the complete spring.

After this operation the leafs are reheated to 1,550 deg. F., and tempered in oil. They are next placed in the draw fire, brought to a certain heat, and peened over a block, right to standard gauges. After cooling they are buffed, and the eye on large leaf is faced on a double disc grinder. The bushing in the eye can be inserted previous to grinding if desired, but this operation is varied, and often the bushing is put in place after first forming to shape.

These steps being completed, the leafs are graphited, and clips put in place. Now comes final assembly, and once everything is locked securely, each spring is tested, then placed in stock. Note that every spring is tested, not merely one in a batch, and the test consists of similar treatment to that which the spring would get on the road when fastened to the car. They figure it is better to break the spring at the factory, rather than on the road, but owing to careful supervision, few breakages occur, even in the tests.

After the plates or leafs are fitted, they are tested to a Brinnel point of 320. This is simply a further check to see that only the best material goes into the finished product. The neatness of the entire factory is a credit to the management, for although springs are somewhat of a messy proposition to handle, the plant is well kept and arranged.

Each furnace is carefully attended to, and a quenching tank is in close proximity to each fire. Oil-fired furnaces are used, and in a year this firm uses over $40,000 worth of fuel oil. Even the bolt bill amounts to $35,000 so one can readily imagine the enormous amount spent on raw material for the springs. When walking through an automobile assembling plant, after once having seen a spring factory in operation, you cannot help but picture the workman busily bending to shape the now completed springs going into the finished car.

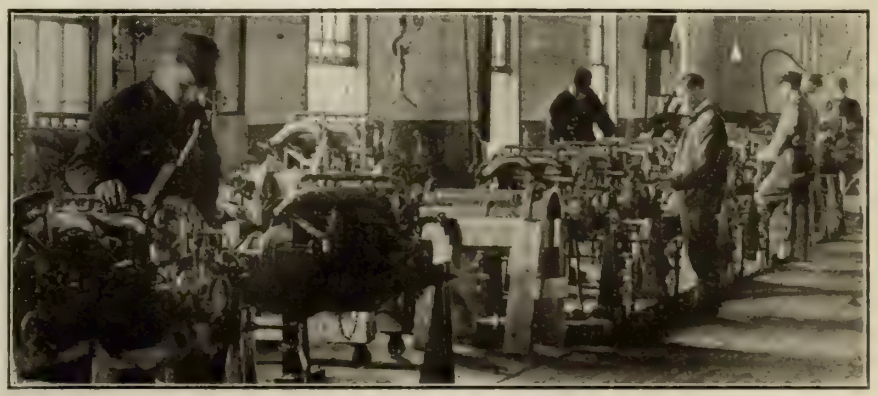
W. Jones, is the president of this company; W. T. Sampson the general manager; G. Hood the sales manager; G. W. Sprague, managing director and purchasing agent; C. D. Smith, Joseph Guttridge, J. A. Fisher, and G. Groome being the shop foremen in the various departments.

SAFETY AND PRODUCTION

(Continued from page 62)

1919, 1920 and 1921. The 1918 file was crammed with accident reports, the 1919 showed not quite so many, the 1920 still less and the 1921 showed a big reduction. The number of accident reports for the first four months of 1922 could be counted on the fingers of one hand. "There is your answer," we were told and, satisfied, we passed on to other matters.

So far as machine equipment is concerned they have upsetters, bull dozers, stock shears, presses of all kinds, die sinking machines, millers, shapers, planers, lathes, electric cranes, electric trucks, locomotive cranes, steam and board hammers, coal elevators and crusher. Crankshafts, cam shafts, axles, in fact all forgings going into an automobile are forged in this plant.



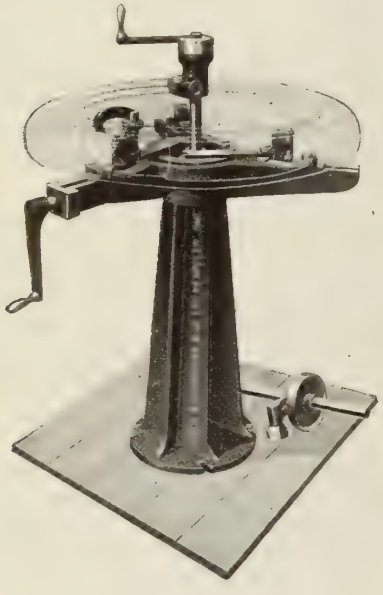
A very good method of supplying forgings to the trimming presses is in use. The parts coming from the hammers are put on to trucks, wheeled onto an elevator and raised to a gallery which completely encircles the trimming department. On this gallery floor are hopper bins and the forgings are unloaded into the bins behind the presses that are set up to trim that particular forging. The forgings are taken out from the lower opening of the bin as needed and the press man gets his supply without ever being bothered by the trucker.

An auxiliary steam plant also forms part of the plant equipment. It is of course only used when the hydro power is not available and the value of this auxiliary power was proven during the severe sleet storms of the past winter. The plant schedule was maintained while other factories were forced to shut down.

A visit to this plant clearly shows the wisdom of careful planning and expenditure of money. From the main offices to the back yard can be found evidence of careful study and wise building. The handling of all material and the comfort of the employees has received equal consideration and it all makes for smooth, efficient plant operation.

The coal situation in Montreal is gradually taking on an acute tone owing to the scarcity of anthracite in many of the yards. Dealers there are not straining themselves to renew their supplies owing to the difficulty of placing orders and the fact that freights are to be lowered on July 1.

Further steps have just been taken to again interest the government in the standardization of parts on agricultural implements. Special permission was granted to Senator A. B. McCoig to take this matter up in committee and at his solicitation another sub-committee was appointed to approach the manufacturers in regard to this matter. This new sub-committee consists of Fred Kay, Missisquoi; J. F. White, London; R. Milne, Neepawa; M. N. Campbell, Mackenzie; D. M. Kennedy, Edmonton, and J. M. Brown, Lisgar.



Showing Block Testing of Motors

New Things in Shop Equipment

TIRE CHANGER

One of the most recent instances in which a new line fits in exceptionally well with the regular production is that of A. B. Jardine & Co., Hespeler, and they are specializing in garage equipment—tire changers, presses, cranes and engine stands—a line which is at once co-operative with that of taps and dies, grinders, drilling machines, blowers and forges—the distinctively Jardine line of tools.

Featured in their garage equipment is a tire changer for which some outstanding claims are made. The principle of operating sliding jaws together with the compensating jaws for contracting

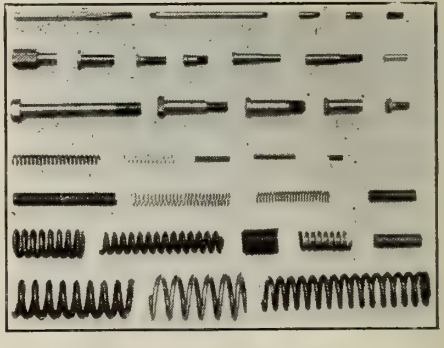
Tire Changer

the rim, and the rollers which operate when expanding the rim, is said to be distinctive, reducing friction to a minimum and make operation very easy on the most stubborn tire. This changer occupies floor space of 36″ x 36″ and weighs 260 lbs.

There is also in the new Jardine line a combination floor and wrecking crane, two tons tested capacity, which may be removed from its base on the floor and mounted on a truck in a few minutes for wrecking purposes. When this crane is in position to take a lift and the handle is raised, the crane is automatically locked to the floor. The floor space is 34″ x 60″. For heavy work such as trucks, there is a floor crane of two tons capacity; another crane of one ton capacity for lighter work and one of a half ton capacity for lifting engines, etc. It is equipped with wheels and ball bearing casters, enabling the workman to move the crane loaded to capacity, over the roughest floor with ease.

The Jardine line of presses includes a 42″ press with or without rack press attachment, 25 ton capacity and a 32″ press, with or without rack press attachment, capacity 25 tons. The rack press attachment is used for light and rapid work.

In Jardine crane and presses the capacity as specified is not a rated capacity but is tested before leaving the works and is absolutely guaranteed to be as represented.



The engine stands include stationary and portable plain types for any motor including three point suspension type; stationary and portable geared for any make of engine and a stationary or portable stand to accommodate Ford and Chevrolet engines. There is also a Beuch motor support for Ford and Chevrolet engines, all having positive locking device on pivot pin.

HAND VISE LATHE

A tool of special interest to garage men has recently been placed on the market. This tool which will be known under the name Ramsdell's Hand Vise Lathe is the first successful device to enable one to make accurately from bar stock without the use of an engine lathe or automatic screw machine milled studs, set screws, cap screws, pins and many other special screws and stubs used in automotive and other machinery. Additionally this tool enables one to wind wire springs with any desired pitch. The tool is here shown cutting a chip from a bar held in the vise. The lower portion of the bar shows where a shoulder has been milled down and the end knurled by the tool. Bar stock up to and including one inch in diameter can be handled, thus enabling the operator to make hexagon head cap screws up to and including ⅝ in.; square, fillister and round head cap screws up to and including ¾ in. and flat head cap screws up to and including 9/16 in. button head up to and including ⅝ in. Other work can be handled up to and including 1 in. diameter. Any required length of screw, stud or spring can be easily made. Each set is furnished with centering bushings from ¼ in. up to and including 1 in. by sixteenths of an inch. Both standard and S. A. E. dies and taps are also part of the equipment.

Hand Vise Lathe

Parts produced in Vise Lathe

This holder is so constructed that the required die may be fitted in the upper portion of the holder and a centering bushing of the correct size in the lower portion. The distance between the center of the die and the center of the centering bushing is 9/16 in., thus giving a long bearing for the stock to be threaded. The stock to be threaded first passes through the centering bushing before being engaged by the die and it is therefore impossible to cut the thread off center. The centering bushing also prevents studs and screws being milled off center. The feeding device is hand fed, thereby allowing the operator to take a fine or heavy chip as the occasion requires. All wearing parts are machined to close dimensions and case hardened. As shown in the photograph the complete set is mounted in an attractive hinged top box with the various parts quickly accessible to hand. This tool is manufactured by the Campbell Mfg., Co., of Worcester, Mass.

The Receipt Stamp Tax

THERE APPEARS to be among business men some doubt as to the details of the application of the new receipt stamp tax. The amendment to the budget makes it necessary for any one receiving ten dollars or over and giving a receipt for same to affix a two cent stamp to the receipt, but doubts are expressed as to whether this is to apply in the case of ordinary cash register slips.

As Mr. Fielding stated in his speech in introducing his amendments that the tax was to be similar to that imposed in Great Britain for many years past, it would seem at first sight that it would not apply to these cash slips which are not signed and which therefore legally do not constitute receipts.

The wording of his bill, however, expressly covers cases of this kind by stating that the stamp is required "whether the same (the note, memorandum, or writing) is or is not signed with the name of person."

In some cases these cash slips have the words printed on them "This is a receipt." Such a declaration by the merchant is an admission by him that he is willing to admit that any person holding the slip has paid him the sum mentioned thereon and he thereby waives any right he might otherwise have to deny having received the money by claiming that he has not signed the slip. In such a case the stamp would undoubtedly have to be affixed, as the slip is admittedly a receipt.

The point in doubt is whether it is also required when the slip is simply a record and does not claim to be a receipt. The general opinion of merchants seems to be that it is not; but judging from the wording mentioned above we are of the contrary opinion, as the words "whether the same is or is not signed" seem distinctly to imply that if any slip of paper marked with the amount paid is handed out the tax is applicable.

The tax is one which will undoubtedly bring in a considerable amount of revenue, the exact amount of which, however, it will be impossible to trace, unless special stamps are insisted upon which is not likely to be the case. For many years in England when the tax was first introduced special stamps were used, but the inconvenience caused by the difficulty of obtaining them when wanted resulted in the postage and inland revenue stamp being amalgamated into one.

Time for a Revision Downward

THE CANADIAN Railway Association, which is composed of the Canadian National, the Grand Trunk, the Canadian Pacific and various smaller corporations and branches of United States organizations, have not been slow to follow the example set by the U.S. railways in giving notice of a downward revision of wages paid to maintenance of way employes.

The reduction is not large when the high wages of railway employes compared with those in other lines of industry is considered. It amounts to approximately ten per cent. and will affect some 30,000 men or about twenty per cent. of the working forces of the lines.

Its importance lies in the tendency it will have to bring about a reduction in freight rates which is one of the heaviest handicaps from which industry in general is suffering at the present time.

Another important factor in retarding a revival of industrial activity is the failure of the building trades unions to see that it would be to the interest of the majority to agree to a revision of wages in accord with the reduced cost of living. The impetus which would be given to construction of new homes by which a reduction would provide regular work for all for a long time to come. The reduction which has taken place in the cost of building materials has already had a considerable effect in this direction, but this effect would be intensified if the unions could only see where their workers' true interests lie. Once we can get freight rates and costs of building down to a reasonable level, another era of prosperity is assured.

Make Goods of High Quality

MUCH AS every patriotic Canadian may deplore it, there is nothing to be gained by shutting our eyes to the fact that sentiment will never succeed in excluding German goods from our markets provided that price and quality are right. The plea of the Canadian manufacturer will have to be, not, "Buy my goods, because the others are German," but "Buy my goods, because mine are better or at least as good and as cheap as the others."

Under the new tariff arrangement duties will be levelled on goods basing their values upon what their value would be in Great Britain or other European countries, disregarding altogether the question of exchange.

That the Canadian manufacturer will need all the protection such a tariff can afford will be apparent when it is remembered that his chief handicap lies in the rates of pay, which are now current in Germany which are the equivalent of some four or five dollars a week at the current rate of exchange, and in the working hours which are seldom less than ten to the day without any weekly half holiday.

How the Canadian manufacturer will fare in his own markets, even with the protection of the tariff, in competition with these conditions, remains to be seen. The question as to whether he can successfully compete in the world's markets unprotected by any tariff does not appear susceptible of a very favorable answer.

The mental attitude of the workman in one of the allied countries, compared with that of the German workman is a distinct help to the German manufacturer.

The former feels that the allies having won the war, he is now entitled to the fruits of victory in the shape of an easy time with good pay. The German, on the other hand, realizes that as the loser in the game he has to pay the piper and must expect to work hard in order to do so. Unless the allied worker can be made to see the untenability of the position he is taking up the winners of victory in the field, may easily become the losers in the industrial struggle.

Steel Market Continues to Show Strength

Iron and Steel Prices Are Firm—Demand Is General and Brisk —Machine Tools Steady, Also Small Tools and Supplies—Pig Iron Quiet, Also Scrap Metals

ORE RATES AND PRICES SHOW SEVERAL CHANGES

THE Canadian steel market continues to show strength. In fact, added strength is now in evidence, with the result that prices are decidedly firm. Iron and steel bars are selling at between 2.90c and 3.00c with the small user paying the latter mentioned figure in practically every case. A few merchants are trying to boost the 3.00c price, but have not been sucessful so far. They claim it should go higher, when compared with Buffalo prices, with duty, etc., added. However, it is one thing to try and another to accomplish and the 2.90c to 3.00c quotation is likely to stand for the next few weeks at least. Even dealers admit as much, that is, those content to sell at these figures.

Practically all lines in iron and steel are brisk, but in many cases. the size of orders is not very large. However, total sales show a vast improvement.

Pig iron is quiet, but the mills are not seemingly very anxious for orders, for they are none too sure how things are going to break in the United States. The present coal strike, and the possibility of a railroad strike, has got them guessing and they seem to be playing a waiting game for the present. Prices remain unchanged.

Non-Ferrous metals have dropped back considerably during the week. but dealers feel this is only a temporary fluctuation due to an over supply on the market.

Scrap metals are quiet and no change in price, either in the above mentioned line, or in scrap has occurred. Until foundries get busier. scrap will not pick up very much.

The machine tool market holds its own, with a report of improvement from some quarters. Small tools are steady but not very brisk. There has been no change in prices of any of these lines.

Oils, waste, steel pipe, boiler tubes, and other miscellaneous lines are about the same as mentioned in last week's report, with delivery on steel pipe slow, and prices firm.

The steel market in the United States continues firm. Production is growing slightly and buying for late deliveries is increasing. Prices are stiffening and pressure for early delivery is increasing.

The present production of steel ingots represents about 75 per cent. of production capacity, but "capacity" is being forgotten under present conditions, as this no longer presents the correct viewpoint.

Premiums are usually paid when securing early deliveries and this practice seems to be increasing somewhat. Reports state that sheets have been sold August and September delivery with a price guarantee. Sellers, however, are indisposed to admit this.

Pig iron continues dull. Consumers expect a decline in prices and are disposed to stay out of the market as long as possible.

Ore prices have now declined 50 cents all round, this making the 1922 schedule the same as that obtaining in the 1917 season. Transportation matters have also been settled and freight rates from mines to lakes are down 10 per cent. The rate charged by vessels is down from 94 cents to 83 cents and these charges are included in the price of ore which is f. o. b. Lake Erie dock. Remaining charges are paid by the buyers of ore. Last season valley furnaces had 8½ cents dock charges for loading cars, plus 91 for line haul. The cost is now 8 cents and 82 respectively.

Toronto

June 21

THE steel market continues firm. Compared with last week it is even brisker and dealers feel the peak has not yet been reached.

Prices.—So far as prices are concerned, they vary accordingly to the size of order, whether the customer is an old standby and so on. For example, iron and steel bars range between 2.90c. and 3.00c. with some dealers trying to get over the 3.00c. figure. One merchant told Canadian Machinery he expected 3.15c. to prevail shortly, but such a statement has to be taken with a grain of salt. There is no question but that the market is decidedly firm, but so long as competition continues to be so keen, the 3.15c figure will not arrive for some time at least. Another merchant laughed when told of this incident and said, "Well—we keep on selling at 2.90c.

No special line seems to be featured, but rather a good general demand exists. Even the dealers are finding the going none too good, for several who have wired the mills for best delivery, have found August and even September quoted. This, of course, is no good to them but it only bears out what we said in th's letter some time ago, viz., "deliveries would soon become more extended and those requiring material should order quickly before the rise and delay occurs."

Following are present quotations. including sheets which are also in strong demand.

Iron bars	2 90 to 3 00
Steel bars	2 90 to 3 00
Reinforcing bars	2 90 to 3 00
Steel hoops	4 00
Tire steel	3 15
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in base	3 50
Small shapes	3 00
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10	4 00
Canada plates, dull, 52 sheets	6 00
Canada plates, all bright	
Galvanized Sheets, No. 28	6 00

Pig Iron—The price still remains $27.15 and there is not much material moving. The mills are not pushing sales, because with the present unsettled coal strike, and the possibility of a railroad strike, they are not anxious to tie themselves up to promises or prices. It is a case of sitting tight until they see which way the cat jumps.

Non-Ferrous Metals— Keen disappointment exists on this market, for after the strength of last week, dealers expected at least to hold their own, if not to show further improvement. Instead of that, the market has sagged considerably during the week and even the old reliable copper has also weakened. Dealers are at a loss to account for it, and the only reason advanced is probably an over supply on the market. Every merchant feels this is a temporary fluctuation and that next week will bring them back, at least, to former levels. In spite of the weak demand, however, prices have not changed and following are existing quotations.

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals—This section is about holding its own. Prices remain the same and what demand does exist is for small quantities. Quite a spread is shown in the Montreal and Toronto scrap prices, but Toronto dealers claim they are at the correct level and Montreal too high. The Montreal figures are based on gross ton, Toronto on net. Montreal representative is investigating this matter closely and next week may see a change in that locality. Following are local quotations:

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	16 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools.— Reports vary on this market. The majority of dealers claim to be merely holding their own, while a few report improvement. Several dealers and manufacturers landed some fair contracts for some technical school equipment lately, but outside of that, the general style of order received is not for a large amount, but usually for a single tool.

Enquiries are coming in fairly good and if optimism counts for anything, there is nothing to worry about, for every merchant feels it is only a question of time before things open up.

Small Tools and Supplies—This market remains steady but shows no further improvement over last week. The demand is general and is scattered over a very wide territory.

Oils and Waste and miscellaneous—Price and demand remain unchanged. Steel pipe is also running at the same rate, the price being firm and deliveries from the mills slow. Boiler tubes are selling but not very briskly, the price being largely a question of the purchaser and quantity ordered. Nominal quotations remain the same, however, as shown on regular quotation pages. There is a possibility that nut and bolt prices may advance shortly. Nothing definite has been done as yet, but we received this from a reliable source and readers can act accordingly. Following are prices on oils, compounds and waste.

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	0 20
Palacine	0 23
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	10 80
Pure turp., single bbls. gal.	1 40
Linseed oil, raw, single bbls.	1 15

WASTE

Mixed colored	14		

Montreal

June 21

BUSINESS has improved in nearly all lines of iron and steel during the week. The increased activity is largely confined to those lines that have been featured during the past few weeks as moving better than other lines. Building construction continues to be in evidence and furnishes a demand for sheets and a variety of small steel products. Merchant bars and structural steel are moving slowly. Machine tools show but little improvement. The non-ferrous metals are also quiet. Scrap metals are also rather listless.

In all lines there is still the tendency to purchase from hand to mouth. During the week inquiries were received by one local firm from two of the largest corporations in the country for small parcels of material, one was for six pounds of aluminum and the other was for a few feet of half inch diameter brass rod. This illustrates the caution that is being shown by all corporations large or small.

Activity along the harbor front, in both inland and ocean traffic, is surprising. Products of all kinds are moving in rather large quantities. In the local machine shops and manufacturing establishments business is gradually improving and with this improvement they are coming into the market for supplies in a fairly satisfactory manner.

Iron and Steel.— Shortly after navigation opened there was a very marked improvement in the demand for black and galvanized sheets. This demand continued for several weeks. Last week was a rather poor week in comparison, but again this week there has been a large business moving in these lines. One jobbing house finds it impossible to keep in stock standard sizes and gauges. They state that at present their warehouse stock is lower than it has been for months. All jobbers are enjoying a lively trade in sheets. Those British mills that are supplying the local trade are well booked with orders and in some cases there is more or less difficulty encountered in getting early deliveries. Some jobbers were fortunate enough to have booked rather heavily early in the year and are doing a big business in these lines.

Merchant bars are moving fairly well and there is a nominal demand for structural sections. Most of the rolling mills are very quiet, but they note an increasing demand for the above lines. Small steel products are moving well owing to the demand for building operations, Plates are very quiet. Railway material is quiet, and there is no material evidence that the railways are coming into the market in the near future, although they may do so with little notice at any time.

Prices remain unchanged, $2.90 being the base figure asked. The mills still ask $2.50 and $2.30 base from the jobbers and large consumers respectively. Local quotations are as follows:

Iron bars	2 90
Steel bars	2 90
Reinforcing bars	2 90
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Little change in the pig iron situation can be reported. There is no change in the local quotation, No. 1 iron selling at $31.80. It is stated that prices have been advanced in all other sections of the country, but that owing to competition existing here no upward revision has been made. Bookings are small. The foundries are consuming but a small tonnage which is estimated at about 10 per cent. of normal.

Machine Tools and shop Supplies.—No change in the machine tool situation has occurred during the week. Sales are still of small tools only. All business is being very aggressively sought Prices remain stationary but the prospects of any material improvement in the near future are held to be remote by the local dealers as there is so much idle equipment in the local shops.

The supply business is very satisfactory. Sales in these lines are increasing of late. Keen competition exists, and although there is but little price cutting, salesmen are very aggressive. The jobbing shops are busier than they have been for months, and are responsible for the good demand. The large manufacturing plants are operating at only a small percentage of their capacity and are not a big factor in this business.

Non-Ferrous Metals.—Business in the non-ferrous metals is rather quiet. Quotations are firm but remain unchanged. The demand is somewhat better than that of last week. No large orders have been received, the business coming from all over the province, and for small lots. The local quotations are as follows:

Lake Copper	17 50
Electric Copper	17 25
Castings, Copper	17 00
Tin	35 00
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metals.—Dealers in scrap metals report that conditions remain much the same as last week. Holdings are not large and the local demand is small. Prices remain the same as they were last week.

Copper, light per 100 lbs.	10 50
Coper, crucible	15 00
Copper, heavy	15 00
Copper Wire	15 00
No. 1 composition	11 00
New brass cuttings	9 00
Red brass turnings	9 50
Yellow brass turnings	5 25
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	13 50
Boiler plate, per gross ton.	9 00
Heavy melting steel	12 00
Axles (wrought iron)	20 00
Rails (scrap)	12 00
Malleable	10 00
No. 1 machine cast iron	23 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	19 00
Mach. shop turnings	4 00
Stove plate	19 00
Cast boring	3 50

Pittsburg

June 21

IRON and steel trade conditions have shown no important change in the past week, there being simply a continuance of the trends previously established. Production is growing a trifle, buying for late deliveries is decreasing, pressure for early deliveries is increasing, and prices are stiffening.

Production of Steel Ingots is now at a rate of about 39,000,000 gross tons a year, against a rate of about 35,000,000 tons of April 1, when the coal strike started, and a production of some 19,000,000 in 1921, that being also approximately the rate of production at the close of the year.

The present production rate of 39,000,-

000 tons a year represents barely 75 per cent. of the productive capacity, but the trade is showing less and less respect for "capacity" as developments furnish a new and more logical viewpoint. It is seen that the country is rather busy, industrially, at the present time, with nearly everybody at work, yet it is doubted whether all the steel being made is being consumed currently, and it is noted that 1912 and 1913, by far the two biggest tonnage years before the war, showed only 30,000,000 tons production each, although industry was well engaged, so that production now is 30 per cent. greater.

Just after the war, when everything was more or less in chaos, men had not gotten their bearings and simply assumed that since the steel making capacity was there it ought to operate, or business conditions would not be right. Of course there were some men with broader vision, but the attitude of 90 per cent. or more of the people was simply that there was the steel industry, called "the barometer of trade" and it had to operate or trade would be poor.

If there are any cases of consumers being unable to operate and fill their orders because they do not receive enough steel, the cases have not come to general knowledge. There is much pressure upon mills by steel buyers for better deliveries, and this pressure upon mills by steel buyers for better deliveries seems to have increased somewhat up to date but it looks as if buyers simply want to be on the safe side, fearing a curtailment in production later on account of the coal strike. The coal strike has lasted for two and a half months, and meanwhile steel production has increased by over 10 per cent.

Technically, the coal strike is two and one-half months nearer its end than it was when it began, but one cannot see any direct evidence of its being any farther along. The union operators and the United Mine Workers each occupy the same position as at the start and neither side shows any signs of weakening. Even the non-union strikes, which were not expected to last nearly as long as the regular union strike, since the non-union men have had scarcely any practice at striking, while the union miners have kept themselves in constant practice for a generation past, are almost as strong as two months ago.

In the Connellsville region there is a little more production, but hardly enough to count for anything. The strike may end next week or it may continue for months. At the beginning the predictions as to its duration ranged from two to six months, and to-day no one has a basis for changing this except to say that the strike will not last less than two and a half months, because the two and a half months are gone.

As to the total turnover in steel products, the market continues to grow less active, and this is the natural trend at this time of year, as July and August are almost invariably very dull months.

Buying for early deliveries, at the premiums that have to be paid in most cases for early delivery, is increasing somewhat, as new wants develop and cannot be met by purchases in the ordinary way. The regular manufacturing consumers who bought ahead are not placing additional tonnages to any extent.

The fininshed steel market is quotable as follows: Bars, shapes and plates, 1.60c to 1.80c; hoops and bands, 2.25c to 2.40c; blue annealed sheets, 2.40c to 2.50c; black sheets, 3.15c to 3.30c; galvanized sheets, 4.15c to 4.30c; automobile sheets 4.50c to 4.75c; wire nails, $2.40 to $2.50; standard steel pipe, 71 per cent. basing discount; tin plate, $4.75.

Mills having regular sheet mill customers in sheet bars have been covering the customers at $35, it being claimed that the sales are made for July only. Whether sheet mills that do not make their sheet bars themselves have been able to sell much tonnage beyond July is a question. There has been much talk of there being a heavy demand for sheets but it is not very clear that the demand is particularly heavy except in the case of automobile sheets, and the automobile trade of course wants its sheets for very early deliveries.

There are reports that sheets have been sold for August and September delivery with a price guarantee, either written in the contract or implied, but sellers are indisposed to admit this. A new departure in the sheet market is the disposal of sheets by consignment to jobbers in New Orleans and Birmingham, and whether this practice will grow and become common is being discussed.

The pig iron market continues very dull. Consumers, of course, expect a decline in prices when coke becomes less scarce and have been disposed to stay out of the market as long as possible. What surprises the trade is that they have been able to stay out so long, and the conclusion is that the iron foundries, as well as the smaller steel works that buy pig iron, are not as busy as are the large steel interests. Quotations, which are now largely nominal remain at $25 for Bessemer and basic and $24 to $25 for foundry, f. o. b. valley furnaces.

As reported a week ago, Lake Superior ore prices for the 1922 season have been developed, at 50 cents decline all around from 1921 prices, making the 1922 schedule the same as that obtaining in the 1917 season. Transportation matters have been settled. Freight rates from mines to the lakes are down 10 per cent., which reduces the range from the Mesabi and Vermillion ranges from 1 to 90 cents. The lake vessel rate is down 11 cents, i.e., the vessel rate proper comes down from 80 cents to 70 cents, and the dock charge at the lower end of the haul is reduced from 14 cents to 13 cents, so that the rate charged by vessels comes down from 94 cents to 83 cents. All these charges are incuded in the price of ore, which is f. o. b. Lake Erie dock, Mesabi non-Bessemer ore being $5.05, now. Remaining charges are paid by the buyers of ore. Last season the valley furnaces had 8½ cents dock charges, for loading cars, to pay, plus the line haul of 91 cents. Now they have 8 cents dock charges and 82 cents line haul.

WELL PREPARED BOOK

"Industrial Diamonds and Their Uses," is the title of a very neat and well arranged booklet prepared by Furniss-Clarke & Co., 32 McGill College Ave., Montreal, P. Q.

The pages are filled with many interesting facts regarding industrial diamonds and Canadian Machinery had the privilege of publishing this material before actual date of the book's release, thanks to the courtesy of Mr. Furniss-Clarke, general manager of the firm, who is the author.

The intention is to get a new book each month, all along the same general ines, but changing the informative matter. Thus, for the first time, those interested in industrial diamonds will be able to secure accurate information on this important subject. The books will be sent gratis to anyone requesting them.

GUELPH'S ACTIVITIES

"WE HAVE IN GUELPH, ONT., a number of industries who are manufacturing parts for automobiles," writes H. Westoby, secretary of the Guelph Chamber of Commerce. They are as follows:—

Taylor-Forbes Co. This firm manufactures engines for Ford and a number of other companies. They also manufacture door-knobs, hinges, and automobile hardware. The value of the plant would be in the neighborhood of 2½ million dollars, but the automobile portion of it could hardly be ascertained accurately.

International Malleable Iron Co. This firm makes malleable iron castings for practically all the automobile companies in Canada. The value of plant and equipment would be in the neighborhood of 1½ million dollars, but only a small proportion of this is applicable to the automobile industry.

F. E. Partridge Rubber Co. This plant is devoted exclusively to the manufacture of automobile tires, inner tubing, and rubber mats. They are capitalized at one million dollars, and give employment to about 450 men at the present time.

Guelph Spring and Axle Co. Make springs for the different automobile companies. About $150,000 would represent the outlay, and the whole of this firm's work is exclusively devoted to manufacturing springs. The number of employees in all of these factories on automobile parts would number around 750.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—	
Silicon, 2.25% to 2.75%	29 15

Production of Steel—Iron Ore to Finished Product

Production Methods Past and Present—Sales and Purchasing Philosophy—Relation Between Purchasing Agent and Salesman —Study of Human Nature Essential, Also Co-operation Between Both Parties

By GEORGE A. SIMPSON

IT IS NOT often that purchasing agents have the opportunity of listening to such an able talk as was given to them the other evening at their monthly meeting in the Board of Trade rooms, Royal Bank Building, Toronto, by George A. Simpson, vice-president of Dominion Alloy Steel Corporation. Mr. Simpson described in a non-technical way, the production of steel from the iron ore to the finished product. He first told of his start in the steel industry in England, mentioning how, as a boy, he went to sea, being an apprentice on a sailing ship, later, on leaving the ship how he happened to get into a small town which had a rolling mill, and being on his uppers, and a fairly good scholar, he applied for a position in the mill.

To use his own words, he did not secure a position, but a job. He started in as a weigh boy, that is to say, he weighed puddlers' iron, and for this he received the princely wage of $1,-75 per week. From then on, he tried his hand at about everything around the mill, including firing boilers, running engines, working around the hollow fires, puddling furnaces, etc., etc., until finally he was operating the steam hammers.

Mr. Simpson very ably described the old time method of making steel, and told how the gangs used to work around the open-hearth furnaces. He pictured to those present, men picking up the scrap by hand and throwing it into the furnace until the charge was complete. He next branched out into the modern method of making steel and without any actual illustrations successfully pictured to everyone present a modern steel mill. Instead of the old time method of charging, he described the new charging machine which is operated by one man. He told how the huge ram runs in and out, picking up a box filled with scrap and pushes it into the furnace, turns it over emptying the scrap into the furnace and returns for another box. In the course of his remarks he mentioned that from fifty to sixty tons of metal could be charged in this manner in a fraction of the time that six or seven tons of scrap could be handled in the old way.

Handling of Ores

His next step was to carry his hearers on to Pittsburgh and other places in the United States where he had worked in the steel mills. All this was exceedingly interesting and he talked to his fellow-laymen giving them a chance to understand in a non-technical manner what he was picturing to them. He then took up the subject of ores and mentioned that at present, the largest percentage of ores used in the making of steel in Canada comes from the United States. He felt that later on with our wonderful mineral resources we might be more dependent on Canadian ore.

After describing the general appearance of the different ores, and how an enormous tonnage was loaded into boats at Duluth and other points in a few hours for their trip down the lakes to the places where they were unload-

GEORGE A. SIMPSON,
Vice-President of the Dominion Alloy Steel Corporation.

ed almost as quickly, how the ore was placed into steel cars for delivery to the furnaces, he mentioned how it came into the furnace yards in a rough looking state, later going to the blast furnace. He went on to describe what a blast-furnace consisted of, and how the burden was placed into the furnace previous to melting. He told how the ore, coke and limestone were charged into the furnace and in a very simple yet efficient manner took his hearers into the interior of a blast furnace. By the time he got through one could almost picture the material being melted.

He also commented on the great care that was taken in supplying the proper mixture, that is. to put in the proper amount of the various ingredients. In fact, he said, it reminded him of a druggist mixing up a prescription, so much of this and so much of that in proper proportions. "You have to put in at the top of the furnace what you hope to take out at the bottom," remarked Mr. Simpson. He then described the old method of casting pig iron when they used to tap the furnace and allow the molten metal to run on to the casting floor and be cast in molds in the sand. He pointed out how much labor was wasted and the large floor space that was necessary for that operation. He next explained the modern method, showing how the molten metal ran direct from the furnace into large ladles, how a locomotive took this molten metal over to a big casting machine which in appearance is very much like an incline railway going up to a considerable height and equipped with an endless sprocket chain to which are attached cast iron molds.

He pictured how the molten metal was poured into these molds, carried up to the top, sprayed with water, then dropped into a car underneath, later being quenched by means of a hose. This report is of course only a mere skeleton of the details into which Mr. Simpson took his hearers. He next described the making of open-hearth steel, explaining how basic pig iron was made, how the ladles were taken to the open-hearth furnaces and so on. He mentioned that a tilting mixing furnace was used when the furnace to be charged was not ready for the hot metal coming from the blast furnace. He showed how this modern method was very much ahead of the old time system, and he so thoroughly explained that there is no appreciable loss of heat as the material passes along, in other words, it is a more direct process and a great saving in time, heat and labor.

Stripping The Ingot

He also explained the Bessemer process and gave a very interesting talk on some experiences he had met with in the various steel mills. He mentioned several important men in the English steel industry whom he had met and taken through American mills, and one striking coincidence was the fact that, when the members of the British Iron and Steel Institute visited the United States as the guests of the American Iron and Steel Institute, he directed a party of English iron masters through the Homestead mills ,and one of the party was a part owner of the mills in which he, the speaker had worked in England as a boy. Thus he had the privilege and satisfaction of showing his former employer one of the largest and most modern steel mills in the world.

From then on he described how ingots were cast, stripped, taken to the

soaking pits and later to the blooming mill to break them down. Again he emphasized the fact that there was very little heat lost in the process, everything being done in sequence so that the greatest efficiency would result. He next pictured the type of rolling mills used, how the ingot was placed on the roll tables and how the men up on the deck, or pulpit as it is called, operated by means of levers a huge roller table which carried the ingot to and fro to the rolls. He caused quite a bit of laughter by remarking that boys could easily handle an ingot weighing from two to three tons unaided where by the old method twelve or fifteen men would be struggling with bars and hooks around a one ton ingot, in other words, said Mr. Simpson, "the modern steel mill is very much of a man-less proposition. You can see the material passing along but very seldom do you see many men around. It is largely a mechanical proposition and the wizardry and bigness of it seems to fascinate and hold those who became connected with the industry."

He went on to describe how the ingots rush through the rolls back and forth and so on until eventually they were reduced to the desired size for further work.

He explained the operation of the flying shear and how it came down at exactly the proper time and cut off the billets to the proper length. After this operation the billets go out into the yard until they are assigned to the various departments to make bars or whatever products in finished form are to be turned out.

He then, in a brief manner described a modern rod mill, how the automatic furnaces were arranged, and how the material being heated in the furnaces was passed through various sized rolls until it would come out the proper size at the finishing end of the operation. He told how this modern method is away ahead of the old method and mentioned that even the material was weighed on a scale after completion, and as the desired amount rested on the scale it clicked and sent the rods or bars down to be bundled, packed and tied, to be later on forwarded to the customer.

He also described the making of wire, and the production of sheets, and mentioned how the sheet bars were sent to the rolls, and told how the sheets were re-heated and doubled. He mentioned that sometimes finished sheets were rolled four at one time and after being sheared, opened up quite easily. He described how this hot rolled sheet was a little rough and how the cold rolling operation polished it. He explained that a one-pass cold-roll and box-annealed sheet meant that the material had been passed once through the cold roll, and later was packed in a large cast iron inverted pot and placed in an annealing furnace. He also described blue annealed sheets and different other grades and the purpose for which they were used. He touched on several other important lines and operations connected with the steel industry which unfortunately we have not the space to describe.

Taken in all, the address was one of the finest talks on the steel industry from start to finish we have ever listened to. After concluding his talk on the steel industry, Mr. Simpson accepted the invitation of the chairman of the meeting to speak to the purchasing agents as a master salesman to the purchasing agent. As our readers are well aware, Mr. Simpson was sales manager for the Steel Company of Canada for many years and can speak with authority on the subject of salesmanship, and this he did, and we feel sure that never before have purchasing agents received so much first-hand information and in such a candid manner.

Relation Between Salesmen and Purchasing Agent

Mr. Simpson told them what he thought the proper relation should be between a salesman and purchasing agent. He stated that he did not know of any two bodies of men who could exert a greater influence to bring about a higher standard of business ethics than the purchasing agents and salesmen. He mentioned that if he were going to be a purchasing agent, the first thing he would do would be to take a course in the study of human nature, "as I believe," he said, "that is one of the greatest essentials of a successful purchasing agent. Know your man, and you will then know whether to place confidence in him or not. Many a purchasing agent has lost thousands of dollars to his company through not watching this very important point.

"The salesman may not be aggressive but he may be sincere," continued Mr. Simpson, "and he may be trying to give you the very best price and conditions to which you are entitled, but through lack of confidence and knowledge of human nature you may lose an opportunity to put through a profitable deal for your company.

"I realize," continued Mr. Simpson, "that you often meet a salesman of the other type, and there again your good judgment and careful study of human nature comes in.

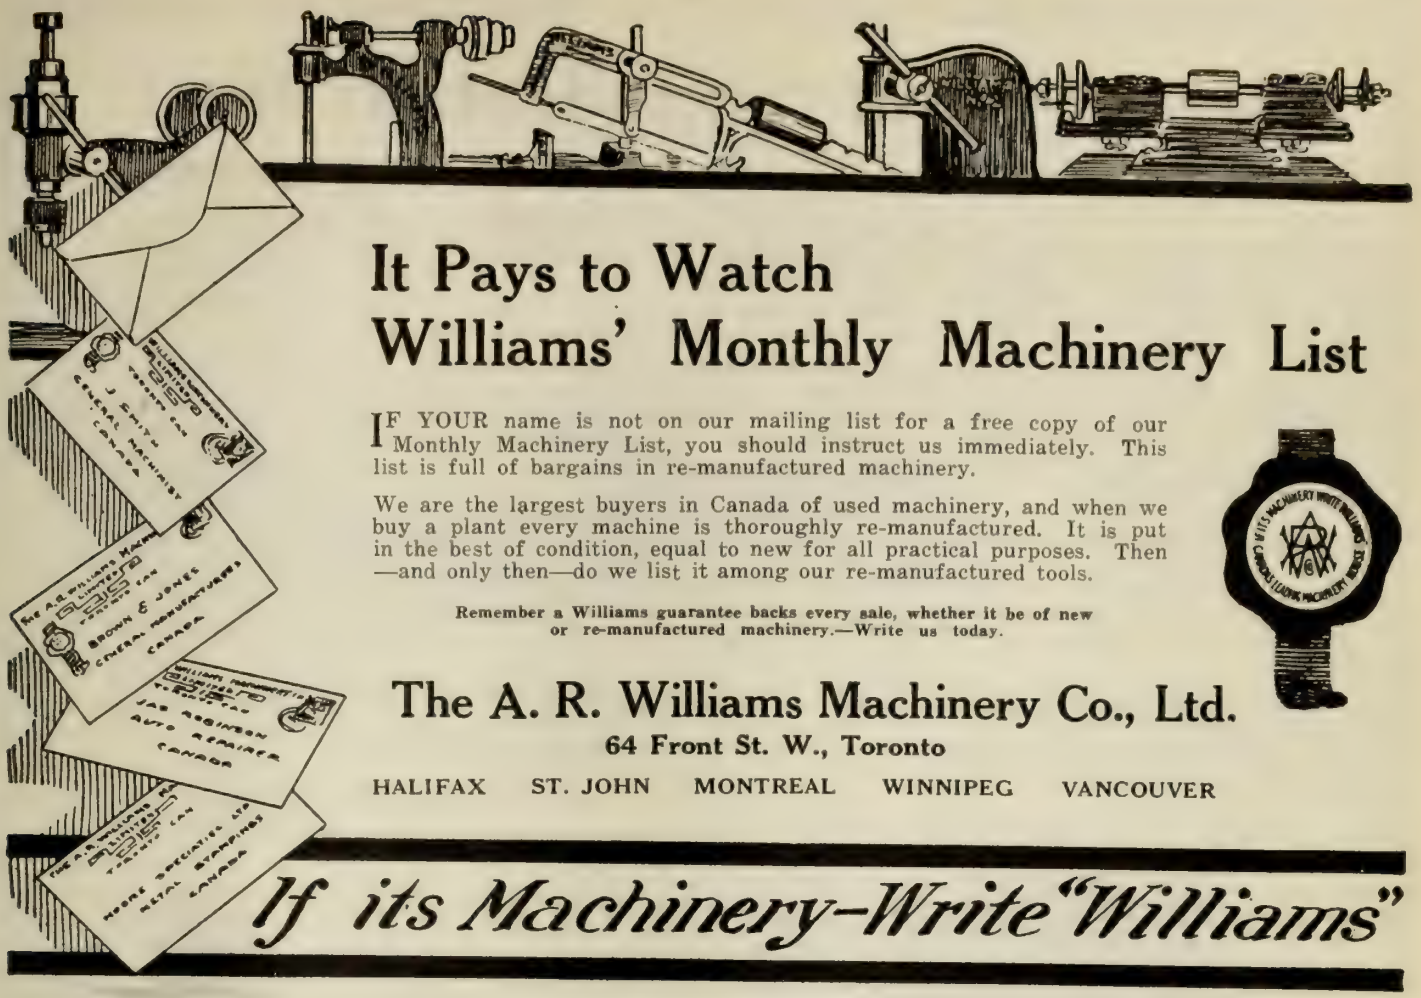
"Never hold a club over the other man's head," said Mr. Simpson, "it is a false and unsound position to occupy. The purchasing agent and salesman should work together in absolute harmony, and the utmost confidence should exist between them. Once you secure the co-operation of the salesman you cannot reckon in dollars and cents the value it will be to you. He will assist you in getting material when you most require it. Sometimes when other sources have absolutely failed."

To prove this point the speaker cited various instances where had it not been for the salesman, the material on orders which was badly needed would not have come through in time to help the manufacturer out. In fact he showed convincingly that plants would have been closed down had it not been for the salesman interceding in behalf of the purchasing agent.

Without going into any further detail on this subject, sufficient to say, the speaker left the impression with his audience, that the salesman should receive the greatest consideration from the purchasing agent, and that in turn, if the purchasing agent did give the salesman his co-operation, he, in, turn, would get the very best price and service possible. According to Mr. Simpson's philosophy, the bond of confidence between the buyer and the seller should be so sound that open orders, "Best Price and Terms" should be the rule, rather than the very extreme exception. He pointed out that in many cases the salesman can be developed into a profitable source of information for the purchasing agent, and that in turn the purchasing agent can often furnish the salesman with information of great value to him. "In other words," said the speaker, "if they work together, they make an ideal team and a mutually profitable one."

After Mr. Simpson had concluded his remarks a vote of thanks was moved and seconded and a hearty round of applause was given to the speaker. The chairman of the meeting in closing said, "Mr. Simpson, it is seldom we have such an interesting and well-attended meeting, and I cannot remember any other meeting where at least a few of our members did not leave before the conclusion of the address. You will notice to-night that no one left the room, which I think is a decided compliment to you." We can heartily concur with the chairman's remarks as the entire address was a very interesting one from our point of view.

MOTORS IN CANADA



There are at present about 500,000 motor cars in Canada, and with a population of approximately 9,000,000 would figure out at one motor vehicle for every eighteen inhabitants. The report of the Dominion government bureau of statistics shows that in the last year over 60,000 new motor vehicles have been licensed. "The most surprising increase," said a provincial government official, "occurred in the western provinces. Saskatchewan, which but a comparatively short time ago was a playground for the buffalo, to-day has 62,638 motor vehicles, mostly automobiles. Manitoba has 40,430, Alberta 38,750, and British Columbia 31,000.

ONTARIO'S MOTOR CARS

Below are the official figures of the number of motor cars now operating under license in the Province of Ontario:—

	Owned by Farmers 1920		Owned by Farmers 1921	
Pas. Cars	155,861	57,429	181,978	64.045
Trucks	16,204	1,273	19,554	1,859

Increase—Passenger Cars 26,117
Trucks 3,350

It Pays to Watch Williams' Monthly Machinery List

IF YOUR name is not on our mailing list for a free copy of our Monthly Machinery List, you should instruct us immediately. This list is full of bargains in re-manufactured machinery.

We are the largest buyers in Canada of used machinery, and when we buy a plant every machine is thoroughly re-manufactured. It is put in the best of condition, equal to new for all practical purposes. Then —and only then—do we list it among our re-manufactured tools.

Remember a Williams guarantee backs every sale, whether it be of new or re-manufactured machinery.—Write us today.

PURCHASE MAJORITY OF MATERIAL USED FROM CANADIAN FIRMS

NO matter what Canadian-made car you drive, ten chances to one the upholstering in it, and the top which covers your head from the blazing sun, was made at the Walkerville, Ontario, plant of the American Auto Trim Co. The more you investigate the automotive industry the more you find it consists of a number of specialized trades, of which trimming is a very important one.

In this plant, which has a total floor space of 160,000 sq. ft. and is valued at a million dollars, we find 350 employees busily engaged in turning out all upholstering parts for a car such as seats, side curtains, tops, etc. Canada receives considerable benefit from this industry because about 80 per cent. of the material used, is purchased in Canada. This includes springs, fabrikod, bows, cardboard, webbing, felt pads, nuts and bolts, tacks, glass, paints, hardware, cotton bats, burlap, etc.

Not only are the various upholstering units made in this plant, but they are also assembled to bodies, these being painted at a later stage and shipped practically in finished condition to various automobile firms. Ford bodies are the feature but other types made are Maxwell, Overland, Dodge and some General Motor work.

The average monthly pay roll is about $35,000, and this year they expect to produce 70,000 auto tops, and 50,000 bodies completely upholstered. Of the 70,000 tops made, about 60,000 of these will be used on Ford cars. The plant is roughly speaking divided as follows: The first floor consists of stock room and offices, and the stock room is admirably well kept. A large number of parts go into the upholstering of a car, but everything is labelled and close tab is kept on the quantity on hand. On the second floor the tops are trimmed. Cutting benches, sewing machines and general trimming equipment are also on this floor. The third storey is used for the first stages of painting while the fourth is used for painting and rubbing. The fifth floor is a sort of general storeroom.

The method of making what is known as a combination binding and cushion welt is very interesting. This welt is the material which goes around the edges of cushions, seat upholstering and so on. The material, in large widths, first passes through a Cameron cutter. This has a series of knives which cuts the material into strips of proper width. After passing through the machine, these strips are wound on a reel, and are taken from the machine to a bench where several small reels are made into one large continuous reel, the ends being glued to make an endless strip.

The next step is to take the goods to the welt forming machine. The material from the large reel passes over hot glue rolls, into a forming die, goes through still further until it meets with a line of good heavy twine, which is so arranged that the cord passes with the material through finishing rolls, and is formed in with welt. This makes a good strong binding, and of course, as the material has passed over hot glue rolls to start with, the pressure of the finish form roll glues everything together securely.

Another operation is the cutting to shape of the different upholstering parts. An electric knife is used, and from 50 to 85 thicknesses of material can be cut at one time. Large rollers at the end of cutting bench, which is extremely long, holds the upholstering fabric. The workmen get a hold of the end of this, walk the length of the bench, then cut off at the roll. This leaves one layer, and the performance is repeated until sufficient layers rest upon the cutting table.

The layout man now takes his standard forms, or templets, places these on the top sheet of fabrics, and proceeds to mark off as many as possible on the area of material presented. Careful thought in this matter has resulted in very little waste, and where possible any fabric left over from the cutting of larger parts is used for smaller pieces.

News From the Industrial Field

A contract for the construction of twelve miles of railway west of Rimbley, Alta., has been given to W. A. Dutton of Winnipeg. The cost will be approximately $225,000.

The general contract for the erection of a pulp mill at Three Rivers, for the Three Rivers Pulp and Paper Co., has been awardd to Thompson Starrett Co., 910 Drummond Bldg., Montreal. The cost will be about $4,000,000.

McDonald Construction Co., Pickford & Blacks Wharf, Halifax, has received the general contract for the construction of the trestle for railway cars and pockets for Geo. T. Vanbuskirk Co. of Halifax.

The Dominion Bridge Co., has secured the contract for the steel work in connection with the $180,000 factory to be erected for the Western Clock Co., at Peterboro.

Lower prices of building materials have stimulated home building in Fort William and many residences of the $5,000 type are being erected. A year ago this type of building would have cost approximately $1,000 more.

The steamship W. Grant Morden, of the Canada Steamship Lines, cleared from Fort William last week for Buffalo with a cargo of 450,000 bushels of wheat. With wheat at $1.23 per bushel her cargo represents a value of $553,000.

Rapid progress is being made by the Barnett and McQueen company in the construction of the two million bushel capacity concrete elevator for the Northwestern Elevator company, in West Fort William. The grain storage tanks are fifty per cent. completed and the contractors expect to finish their contract early in August.

Fire loss in Fort William for the month of May totalled $20,541.50, the principle item being the loss incurred in the fire which damaged the plant of the Northern Engineering and Supply Co., to the extent of approximately $18,000, including building and stock.

The Fegel's Construction Co., Fort William, have been awarded the contract for the construction of a concrete and brick grain elevator for the Pillsbury Flour Mills Co., at Atchison, Kansas. Material is now being assembled and erection will be commenced immediately.

W. H. Bischoff has rejoined the staff of the Dominion Iron and Steel Co., and will take the office of general superintendent. For the past three years he has been with the Lubin Iron and Steel Co. of Coatesville, Pa., prior to which he was assistant superintendent to H. E. Price at the Sydney plant of the Dominion Iron and Steel Co.

Winnipeg, Manitoba.—In the year 1921 there was a total of 38,566 tons of binder twine available for consumption in Canada, of which 16,176 tons were manufactured in Canada and the remainder imported. The value of binder twine and rope manufactured in Canada last year was $6,297,142; exports $1,194,475. Imports were valued at $7,372,691, while the value of total available for Canadian consumption was $12,475,358.

Ottawa.—The tender of Alex Garvock in the sum of $294,782 on the masonry, brick and carpentry work for the new civic hospital was accepted by the city council and the contract awarded at that figure. The council also awarded a contract for a five-ton street flusher to the International Harvester Co., at $9,240.

Ottawa.—The last of the saw mills in the Ottawa Valley got under way on Tuesday, June 6, when the Shepard and Morse plant commenced operations, giving employment to about 165 hands. The opening of this mill was postponed about a month on account of high water, which, early in May, caused the breaking of several log booms owned by the company.

The Board of Trustees of the Ottawa civic hospital will recommend to the city council that the contract for the electric wiring of the new hospital be let to Fred Wilson at $33,527, that the contract for heating and ventilation be let to W. G. Edge Ltd., at $105,581, and that for the plumbing and drainage to The Garth Co., of Montreal, at $111,000; these being the lowest tenderers for the work.

Shawinigan Falls, Quebec.—A machine building to house two newsprint machines, each of which will have a width of 228 inches, is being erected by the Belgian Industrial Company here. Only one machine will be installed at the present time and it is estimated to have a daily capacity of 80 tons. The expenditure involved in the erection of the building will be about $1,000,000.

Ioco, B. C.—The town of Ioco has sprung into existence in a single year through the location of the Imperial Oil Company's refinery here. Where a little more than twelve months ago was a tangled jungle more than one hundred modern residences have sprung up. The town is practically completed with all modern conveniences installed and operating. The company's wage disbursements at the refinery now total $750,000 a year.

Nelson, British Columbia.—The Consolidated Mining and Smelting Co., has announced the immediate commencement upon the construction of a 500 tons concentrator at Kimberley. The plant will be ten times as large as the largest concentrator in the Kootenay country with the exception of that at Trail and will cost more than $1,250,000. It is expected it will be ready for operation early in 1923.

Toronto, Ontario.—During May construction contracts awarded in Canada, according to McLean's Building Reports, Ltd., amounted to $34,827,300, compared with $29,428,400 in April and $26,859,500 in May, 1921. This is the second largest monthly figure on record since 1914. The value of contemplated new work reported during May was $28,871,500.

BUSINESS FOUNDED OVER THREE GENERATIONS AGO

(Continued from page 44)

Coming to the assembly line, we find that they follow the recognized style of Automobile Assembly, viz., rivet the frames at their plant, then start assembling to these frames the springs, axles, etc. There is no need to go into the assembly step by step, as that has already been explained in another article in this issue.

The process is practically the same. The motors are then assembled to the frame, and electrical units added. Before placing the engine on the chassis it is tested on blocks as shown in one of the illustrations accompanying this article.

Once the frame is complete, the body is placed in position, after which a test run is made. Special runways have been effected which are so inclined that the car gets an actual hill test. Every car tester is an inspector, and without his O. K., the car is not allowed to pass. During the assembly process periodical inspections also take place, and should any defect occur it is instantly removed. When a car is sent to the shipping department it must be ready for the owner to drive.

To show the importance of this industry to not only its locality, but to Canada, the following figures are appended. Every year this firm pays approximately in wages, buys from other Canadian firms, goods valued at approximately one million dollars and keeps in employment in Chatham alone, about 700 men. This last figure includes other firms making material for use in the finished car. Robert Gray is president and general manager, William M. Gray, vice-president and general manager, while J. Fairbrother attends to the sales end of the business.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN **CONNECTICUT**

Canadian Agents:

Williams & Wilson, Ltd. Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, St. John, N.B., Halifax, N.S., Vancouver, B.C.

Montreal, P. Q.—G. and J. Weir (Canada) Ltd., have just completed in their local shops two large boiler feed pumps, which are to be shortly installed in the new Mount Royal Hotel, where they will feed the two thousand boiler horse power that is being installed there at the present time.

W. M. Tilley, K. C., of Toronto, has been appointed a director of the C. P. R., filling the vacancy caused by the death of Sir John Eaton. Mr. Tilley has been filling the position of consulting council for the railroad from the time the office was created in December, 1918.

Announcement has been made that the Lyall Construction Co. of Montreal have obtained the contract for the continued construction work on sections 3 and 4 of the Welland Canal. Prior to the letting of this contract the work had been carried on by day labor under contract of Quinlan Robertson Co.

Plans for a unique bridge to span the Detroit River, between Detroit and Walkerville, have been prepared by Dennis H. O'Meara, a Detroit engineer. The bridge specifications are highly interesting as they call for large office buildings at both approaches to the bridge the stores located in the piers. The bridge will have a width of 125 ft. and will cost in the aggregate about $40,000,000.

Montreal, P. Q.—Two Canadian Goverment Merchant Marine steamers are at present in Montreal Harbor laid up. These are the Canadian Ranger and Canadian Rancher. Four other Canadian Government Merchant Marine steamers have been laid up for some time past, but are about to be commissioned for trips to Glasgow, Cardiff, and Swansea.

Montreal, P. Q.—The Bailey Meter Co. Cleveland, Ohio, opened up a Canadian factory in January 1922. They have well established themselves in the last six months, sales have been increasing and the outlook for the future is considered very bright. Practically all parts are made in the local factory, only a few being imported from the parent works. It is hoped to soon have the shop arranged to take care of all the manufacturing, and the range of meters covers the complete range of boiler requirements.

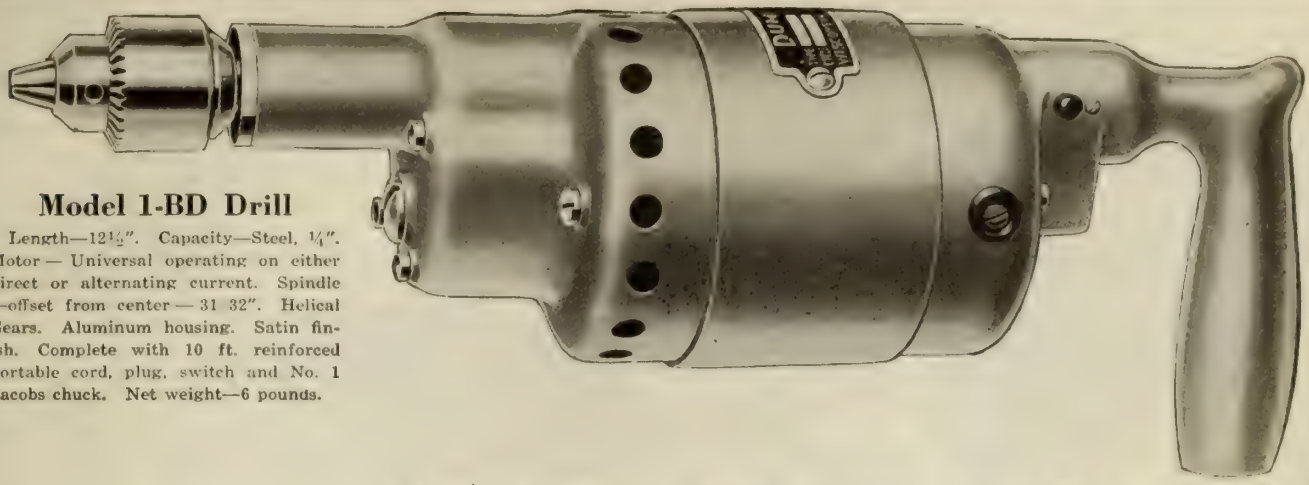
J. R. Burpee, of the firm of D. C. Burpee and Son, Devon, M. B., has just returned from a trip to Presque Isle, Me., where he successfully negotiated a contract for the rebuilding of the power plant of the Maine and New Brunswick Power Co. at Aroostook Falls. He also secured contracts for the construction of four miles of railroad for the Aroostook Valley Railway Co. It is estimated that the value of the contracts will approximate $200,000. D. C. Burpee and Son have recently completed the construction of the substructure of the new international bridge across the St. John River at Edmundston.

The manufacturers of pulp and paper in Canada have gone on record through the Canadian Pulp & Paper Association as being in favor of a general reduction in freight rates. Their statement which goes into the matter very fully is based on eight separate claims, and is now filed with the select committee of parliament dealing with the problems. It favors a revision of freight rates to the levels that were prevalent prior to September 13th, 1920, which it is declared would still allow the railways to charge rates approximately 42 per cent above those in existence before the war.

Montreal, P. Q.—On Saturday morning, June 10th, 225 representatives of the Rochester N. Y. Chamber of Commerce, with other guests from that city as well as representatives of various Montreal Trade Organizations, were the guests of the Montreal Harbor Commissioners on the Steamer "Three Rivers" for a tour of the harbor. The guests gathered about ten o'clock Saturday morning at the foot of McGill St., and boarded the steamer. The tour included a trip down the whole thirteen miles of harbor front, with an inspection of the cold storage plants. The grain handling facilities, as well as the cold storage capacity, were points of particular interest to the visitors.

Ottawa.—Building permits for the month of May more than sustained the promise of activity in the building trades indicated in the earlier months of the year. For the first five months of 1922 the total has now passed the two million dollar mark. In May 189 permits were issued calling for new construction having an estimated cost of $867,351, which is an increase of $625,201 over the corresponding period in 1921 when 96 permits were issued. The total for the first five months of 1922 is $2,017,296 with 461 permits granted as against $1,000,385 on 245 permits in the same months last year. Thus the increase this year for the five months period over last spring is approximately one hundred per cent. both as regards the number of permits issued and the estimated value of new construction. The largest permit issued during May was for the new Hydro Electric plant to be erected on the corner of Carling Avenue and Bank Street which will cost in the neighborhood of $181,000.

Montreal, P. Q.—At the session of the Dominion Council of the Navy League held recently in Montreal, Mr. Sam Harris, the newly elected president, expressed himself in no uncertain way along the line of Canada's need for increased foreign trade. He stated that he would like to see the Navy League a real factor in promoting this branch of commerce. He concluded his remarks by stating that he was perfecting plans to provide an advertising ship for Canadian goods. He hoped that he would be able to make arrangements to have this ship tour the seven seas and act as a national marine drummer for the Dominion. He stated further that he believed the move would prove worth its weight in gold to Canada in trade returns, and he hoped to see it sail on its advertising trip before another year had passed. The visiting members of the Empire often asked him why Canada did not extend her trade. The only answer to that question, he thought, is that it was due to apathy. Leadership is needed and the Navy League is now going to give this leadership in a practical way.

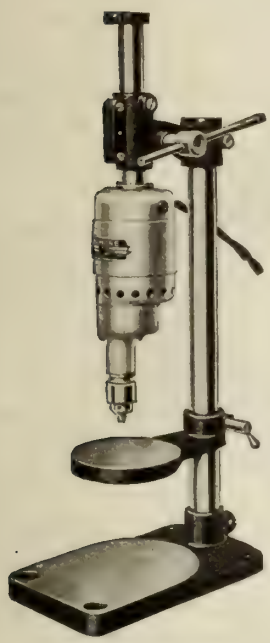


A new era in the use of airplanes for forest and similar air observations was marked recently, by the arrival at Lachine of the Amphibian Viking airplane of the Laurentide Air Services, recently organized, which stopped off for a short time on her way to Northern Ontario to engage in Government service in aerial observation and photography work for the Ontario Government. The Amphibian Viking is the first flying vessel of her class to reach Canada and represents the latest thing in post-war airplane construction both as to the plane itself and its engine. The machine has a capacity for four or five passengers with a pilot and a quantity of baggage in addition. It has a speed of over 100 miles an hour and when in a hurry can do better than this. It is equipped with a 450-horse power engine of the Napier Lion type which is the latest British type of airplane engine.

Montreal, P. Q.—The Montreal Tramways recently conducted a large number of its employees, including executives and many members of its various office staffs, over its different properties in the city. The sub-stations, power houses, shops and barns were visited and the general functioning of these various units explained. The greatest interest was manifested in the Youville shops, which are completely equipped for the entire construction of cars. At present no car building is in progress but the shop is taking care of all repairs and of the installation of the various pieces of accessory equipment that are rapidly being standardized on all up-to-date tram cars. At the shops it was learned that about 900 cars are in daily use in the city of Montreal.

The trip was planned with a view of educating the office staff of the Company so that they would better appreciate its varied activities and could take care of their various duties in a more intelligent manner.

WORKING TO CAPACITY



The Auto Specialties Mfg. Co., Windsor, Ont., was opened for business in August 1920, and has since developed rapidly in the making of malleable iron castings. Their plant covers approximately 60,000 square feet, is built of concrete and steel, equipped with labor saving devices and up-to-date machine equipment. A varied line of castings is made for agricultural, railroad, and automotive industries, and production has been up to capacity now for some months.

Model 1-BD Drill

Length—12½". Capacity—Steel, ¼". Motor — Universal operating on either direct or alternating current. Spindle —offset from center — 31 32". Helical Gears. Aluminum housing. Satin finish. Complete with 10 ft. reinforced portable cord, plug, switch and No. 1 Jacobs chuck. Net weight—6 pounds.

Handy—Efficient—Powerful

Model 2-BD Bench Drill

Motor specifications identical with Model 1-BD.
Height—20½".
Stroke—3¼".
Rack and pinion feed.
Capacity—Steel, ¼".
Drills to center of 7⅞" piece. Ball Bearing thrust. Aluminum housing. Adjustable table. Complete with 10 ft. reinforced portable cord, switch, plug and No. 1 Jacobs chuck. Net weight 21 pounds.

DESIGNED by men who know the practical advantages of small, light tools that get to the spot where needed without waste of time, Dumore Drills save time, money and energy. Equipped with perfectly balanced motors, Dumore Drills are accurately built and have an almost unlimited range of usefulness. For speed and accuracy on fine and sensitive jobs Dumore Drills will supplement the work of your big machines—adding to the capacity of your shop and cutting down production costs on many classes of work.

Send for details of how you can use Dumore Drills to advantage.

PROSPECTS FOR BUSINESS IN VARIOUS COUNTIES

JAMES WEIR of the firm of G. & J. Weir, Glasgow, Scotland, was in Montreal recently visiting the Canadian headquarters of his firm's activities. Mr. Weir has almost accomplished a trip around the world in the interests of his business. He states that industrially France is in good condition, and that she is in a fair way to come out of the reconstruction period stronger than ever before. Germany has less unemployment than any country Mr. Weir visited. He says that labor is putting in long hours and that it is well paid. A large number of the skilled workmen have acquired their own residences since the war. The number of home owners is increasing very rapidly among the industrial workers and thrift is everywhere in evidence among the factory workers, and in practically every instance the savings of the family are invested in homes or other ways equally as safe.

Mr. Weir had occasion to visit Italy, as an Italian firm had offered to sell their plant to his firm. Conditions there were very bad, as far as the metal working industries were concerned, and for that reason it was not deemed advisable to extend manufacturing activities in that country at present.

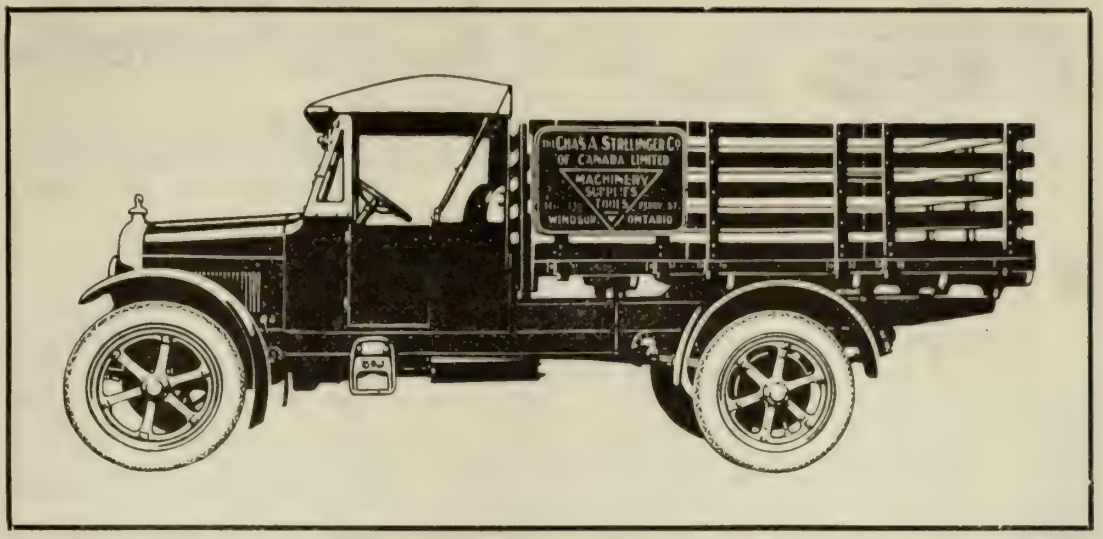
In India prospects for better business in his line were good. In the Straits Settlements and Burmah conditions were very encouraging. Several large pumping installations were inspected by Mr. Weir. His firm had not only manufactured the pumps but had been called in, in an advisory capacity, to discuss the various propositions, which were to pump oil great distances. One installation called for pumps to force oil through several hundred miles of pipe across a desert. The Weir pumps were handling the work satisfactorily.

In Japan this company have an extensive manufacturing establishment, for the last two years has been very busy, and only now is running into the trade depression that made itself manifest in America two years ago. It was stated that for several years the Weir Co. had done ten times the business in China that it had done in Canada.

Mr. Weir was very enthusiastic about the radical improvement that had been made in the parent factory in Glasgow. Automatic machinery and labor saving devices had been installed in every department of the works. In the foundry it is now possible to employ girls to take care of the major part of the moulding operations. Costs had been cut in two in some departments, and in no place were greater savings made than in the foundry. The firm were now ready to make a considerable reduction in quotations on their product. For the first time in the history of the firm the parent plant was making certain parts cheaper than the Japanese plant and these parts are now being shipped to Japan. Mr. Weir's impression was that business was now on the upgrade.

RUST NEUTRALIZER

The American Chemical Paint Co. of Philadelphia, Pa., state that they have perfected a system whereby such work as automobile bodies, or any materials that are soldered, metal finished and painted, may have these operations performed with a minimum amount of rust to be removed in the paint room. This process has been in the course of development for several years and has finally reached the point where it has become an economical and commercial asset. The process consists in a special soldering flux called Flosol. One of its advantages, it is claimed, is that it both cleans and fluxes at one operation, and that it is no longer necessary to use raw acid to remove the rust and dirt, or to scrape the surface with an abrasive. It is claimed that work soldered with this flux is practically free from cells and pockets which break during the painting operation. Flosol is neutralized by a weak solution of Deoxylyte for the purpose of preventing oxidation before it can actually form. It is claimed that this property of neutralization of rust formation eliminates the possibility of defects under the paint.



JOIN ADVERTISING FIRM

Major W. J. Baxter, on June 15th joined the directorate of McConnell & Ferguson, Limited, advertising agency, at London, Ont. Major Baxter was born and educated at Windsor, and left the city editor's desk of the old Windsor Record in 1914 to take a commission as lieutenant in the 18th Battalion. After distinguished services in France, where he was awarded the Military Cross, and on demobilization, he became secretary of the Essex Border Utilities Commission. He resigned in March, 1920, to take control of the advertising department of the Ford Motor Co. of Canada, which he now gives up to join the staff of McConnell & Ferguson, Limited, where his wide experience should be of great value to advertisers in general.

DURANT ACQUIRES WILLYS PLANT

W. C. Durant, head of the Durant Motors Co., has purchased the plant and holdings of the Willys Corporation of New York, for the sum of $5,525,000. It is reported that the object behind this move is to acquire a ready equipped plant for the manufacture of the new Star car, plans for the building of which have been completed.

The recent report of Elmer C. Dover, asst. sec'y of the treasury at Washington, on existing business conditions in America, after a tour of 22 States, was of a very encouraging nature. Mr. Dover's trip was made to survey conditions, and conferences were held with prominent business men. He is reported as having told the President that, in his many conferences, he had not heard one dissent from the general opinion that business was picking up rapidly.

G&J

Built for heavy loads and fast hauling, G & J trucks above all else are profitable hauling units. They pay their way from the start.

Their rugged durability insures a running life of 100,000 miles and more, which spreads their cost over many years. 20 to 25 miles from a gallon of gasoline - 250 miles from a quart of oil (on the one ton Speedtruck) tells the story of their economy.

The organization which builds the G & J is amply well financed. They have made a heavy investment to insure efficient, economical manufacturing, and the permanency of the truck.

Any G & J dealer, and factory branches in Montreal, Toronto and Hamilton will be glad to furnish the facts on what G & J motor transportation will do for your business. *Write for a folder.*

The Lion and The Mouse

DO YOU remember reading in the school books about the great big lion who was caught and trapped in a gigantic net by hunters? Then along came the little teeney mouse who nibbled away at the netting and was successful in setting the lion at liberty again. The net was too strong for the lion to break but the constant nibbling of the mouse, breaking mesh after mesh, was able to perform the seemingly impossible.

A person who is not subscribing to CANADIAN MACHINERY is in exactly the same circumstances as the lion imprisoned in a corner—not being able to enjoy the freedom of expanding his capacity for knowledge.

CANADIAN MACHINERY acts as the mouse. Week by week it will give information—which, on account of the lack of it, has tied you up in an industrial way—will nibble away the meshes, one at a time, that are keeping you from getting the results you want.

Ask us to send you a sample copy. It will not obligate you and it will be a pleasure to us.

CANADIAN MACHINERY,
143 University Ave.,
Toronto, Canada.

Please send me a sample copy of your paper and oblige.

2013, 2016 3 Leblonde 17" x 6" Rapid Production with C/S.
2017 1 Reed 14" x 6" Extra Heavy Duty with C/S.

HACK SAWS

661 1 Peerless 6" x 6".
951 1 Perfect No. 3 6" x 6".

TURRET LATHES

1031, 1040 4 No. 3 Foster, capacity 1 5/8 in. spindle C/S.
1041, 1043 3 No. 2 Foster, capacity 1 1/16 in. Spindle C/S.
2023, 2043 20 16" x 16" Bliss Heavy Duty.
2044, 2054 10 No. 2 Foster with round turret, capacity 1 1/16 in. spindle, C/S.
2055, 2058 3 No. 3 Foster with round turret, back geared capacity, 1⅝ in. spindle, C/S.
2061, 2065 4 No. 3 Foster with hexagon, turret, back geared, capacity 1⅝ in. spindle C/S.
2065 1 J. & L. 15" Turret, round turret, 1¼" hollow spindle.
2067 1 16" x 6' McGregor-Gourlay Turret Lathe.
2068 1 18" x 6' McGregor-Gourlay Turret Lathe.
2069 1 20" x No. 4 Bullard with hexagon turret.
2070, 2070a 2 16" Warner & Swasey Geared Head.
2073 1 17" x 6" Davis Lathe with round turret.
819 1 Oliver 18" Turret with C/S.
818 1 B. & O. 16" Turret with C/S.
815, 816 3 Davis 24" Turret Lathes with power cross feed.
1 Warner-Swasey Turret Lathe No. 6.

GRINDERS

590 1 Bench Type Double End, two stop cone pulley on spindle, no C/S.
1079 1 Wells Toolroom Grinder.
1067 1 Bench Type Double End, single pulley on spindle no C/S.
1069 1 Gardner No. 24 Grinder.

GRINDERS—(Cont'd)

1070 1 Double End Emery Grinder on pedestal, two step cone pulley on spindle, 1" dia. spindle, C. S.
2109, 2110, 2 Perfect No. 6 pedestal Grinders.
2117 1 Sellers 5/16 x 3" Drill Grinder.
898 1 Lafayette Universal Motor Driven Tool Grinder for lathe work.
1064 1 Symington Plain Grinder C/S.

DRILLS

1 Reed Four Spindle Drill Press.
1048 1 Barnes 15" Sensitive.
1065 1 Perfect 14" Sensitive.
1085 1 Perfect 15" Sensitive.
954 1 Edlund 15" High Speed Ball Bearing Drill Press.
675 2 Woodward 4 Spindle Drill Presses.

SCREW MACHINES

1057, 1058, 1059, 3 Acme No. 55 4 Spindle Automatics.
1093, 1094 2 Garvin No. 1 Wire Feed C/S.
2071, 2072, 2 Warner & Swasey No. 6 with geared head, automatic chuck C/S.

ENGINE LATHES

1047 1 Cincinnati 16" x 8' D.B.G. screw feed, chuck, 2 face plated C/S.
1073 1 L'Blonde 17" x 6" S.B.G., Q.C.G. rapid production rod feed, chuck, face plate, C/S.
1038 1 13" x 5" Lathe Chuck face plate and C S not screw cutting.
1081 1 Leblonde 16" x 6' S.B.G. Q.C.G. chuck, face plates, Screw Feed, C/S.
1082 1 Hamilton 16" x 8' S.B.G. Q.C.G. screw feed chuck, face plates, C/S.
2018 1 Stevens 16" x 6' Engine Lathe screw cutting C/S.
2019 1 McGregor-Gourlay 16" x 7" Engine Lathe, screw cutting C/S.
2020 1 Stevens 16 x 8 Engine Lathe, screw cutting C/S.
2021 1 Stevens 18 x 8 Engine Lathe, screw cutting C/S.
812 1 Putnam 36 x 18" S.B.G. Screw cutting, face plates C/S.
810 1 McKechnie-Bertram 20" x 10'. S.B.G., face plates C/S.
666 1 Rae 18" x 8" D.B.G Q.C.G. face plate C/S.

BUFFING MACHINES

051-3, 3 Perfect 36" Pedestal Type 1¼ Spindle.
627 1 24" Perfect 36" Pedestal Type 1" Spindle.

TAPPING MACHINES

1063 1 Ricker Schaufer ⅜ Friction feed.
733 1 Burke Bench Type, horizontal ¼" capacity.
602 1 Burke Bench Type horizontal ¾" capacity.

PRESSES, PUNCHES & SHEARS

944 1 Greenard No. 3½ Arbor Press.
742 1 Niagara No. 3 Arbor Press, pedestal type.
741 1 Niagara No. 3½ Arbor Press, pedestal type.
822 1 Stiles No. 172 Punch Press.
1020 1 Bench Type Punch.
1021 1 Bench Type Shear.
2108 1 Toledo No. 57½ Back Geared Power Press, 4 tee rods, 12" stroke, 140 tons cap. 6" Crank shaft, 24½" between uprights weighs approximately 35,000 lbs. Also a number of Bliss Inclinable Presses.

BLOWERS

A number of Buffalo, Sheldon, Soot Blowers of varying sizes and capacities.

PUMPS, ACCUMULATORS

834 1 Vertical 2 plunger, hydraulic 2½" dia. x 6" stroke 1¼ inlet and d charge.
813 1 Northey Duplex, 6" x 4" x 7".
780 1 Goldie-McCulloch, 2" suction 1½" discharge.
799 1 Smart-Turner 4½" x 2¾" x 6".
2090 1 West Tire, No. 3, 2 cylinder plunger pump.
2091 1 Gould Triplex Plunger Pump.
2092 1 Perrin Triplex Plunger Pump.
2093 1 Small Size Two Plunger Pump.
2119 1 Hydraulic Accumulator, 6 x 8 ram, capacity 10 Imperial Gallons, 1500 lbs.
2137 A number of lubricating pumps for use on Lathes, etc.

MOTORS AND ELECTRICAL EQUIPMENT

1031 1 Lincoln 20 H.P. 3 phase, 60 cycle, 220 volts. 1200 r.p.m. with base and pulley.
634 1 Can. Allis-Chalmers 5 H.P. 3 phase, 60 cy. 550 volts 1200 r.p.m. with base and pulley.
2096 1 Robins & Myers ½ H.P. 1 ph. 25 cy. 110 volts.
2097 1 Westinghouse 50 H.P. 3 phase, 25 cy. 550 volts with base and pulley.
2096 1 Chapman Walker 40 H.P. 3 ph. 25 cy. 550 volts with base and pulley. 750 r. p. m.
1 Westinghouse 35 h.p. motor, 3 ph. 25 cy., 550 volts, with base and pulley.

MISCELLANEOUS

2099, 2102, 3 Strong-Carlisle-Hammond Continuous Annealing Furnaces, 22" long x 3" x 2½" opening.
2103 3 Strong, Carlisle-Hammond Furnaces
2106 for heating drop forge work.
2127 1 Brown Pyrometer 2000° Fahr.
2153 2 Southwark Hydraulic Physical Test-
2154 ing Presses, 2000 lbs. per sq. in. pressure, 2 column type fitted with intensifier ram, revolving table guard and suitable drain basin, mounted on pedestal and arranged for single lever control.
2155 Metalwood Hydraulic Testing Press similar to above.
1032 1 Jardine No. 50 Power Hammer.
1019 2 Sand Riddles.
946 1 Bellevue Oil Furnace.
888 1 Gas Furnace, 12" x 15" x 8" two burners, size of door opening 1"x8".
689 1 Gas Furnace 18 x 11½ x 8" 2 burners, door opening 10 x 8.
2113 2 Bertram Stenciling Machines
2114 Steel.
2115 1 Holden Morgan Stenciling Machine.
2116 1 Burring Machine.
2118 1 Four pt. tapalog complete (Wilson-Maulin.)
2121 3 Brantford Counter Scales
2123, 2124, 2125, 2 LeVilbiss No. 13 S.M. 152 Internal Varnishing machines.
Quantity of Wood Split, Steel Split Pulleys, Hangers, Belting, various sizes
1 Blacksmith Forge.
1 small Anvil.
1 Barrett 15 ton jack
1 Garvin No. 1 Slotter.

CASH REGISTER WANTED—SINGLE DRAWer. Receipt printer. Must be in excellent condition. Box No. 807L Canadian Machinery.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force can not replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments for machinery equipment.

Armstrong Adjustable Boring Tool

This tool will be found very handy in the Tool Room. It exemplifies to a remarkable degree the principles identified with all Armstrong Tools in its convenience, adjustability and rigidity, and is well adapted to a very wide range of work.

The Holder is easily adjustable to different heights and will hold bars of various diameters. The Bars are made from high carbon steel seamless tubing of heavy gauge and are extremely stiff. The Cutter can be adjusted and solidly fixed at various angles for boring, facing or turning.

Send for Catalogue B-20.

A file cannot be resharpened. Yet it is just as imperative for a file to be absolutely sharp as for a saw or a chisel.

It pays to discard a file at the first sign of wear, and get a new one.

Maximum sharpness means minimum time and effort on a filing job.

These brands stay sharp for a long time, giving fullest service for money spent:

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

STANDARD—Not Just Tubing

STANDARD Steel Tubing offers distinct advantages, including that of economy. It can replace various structural shapes satisfactorily and adds greatly to the appearance of the product.

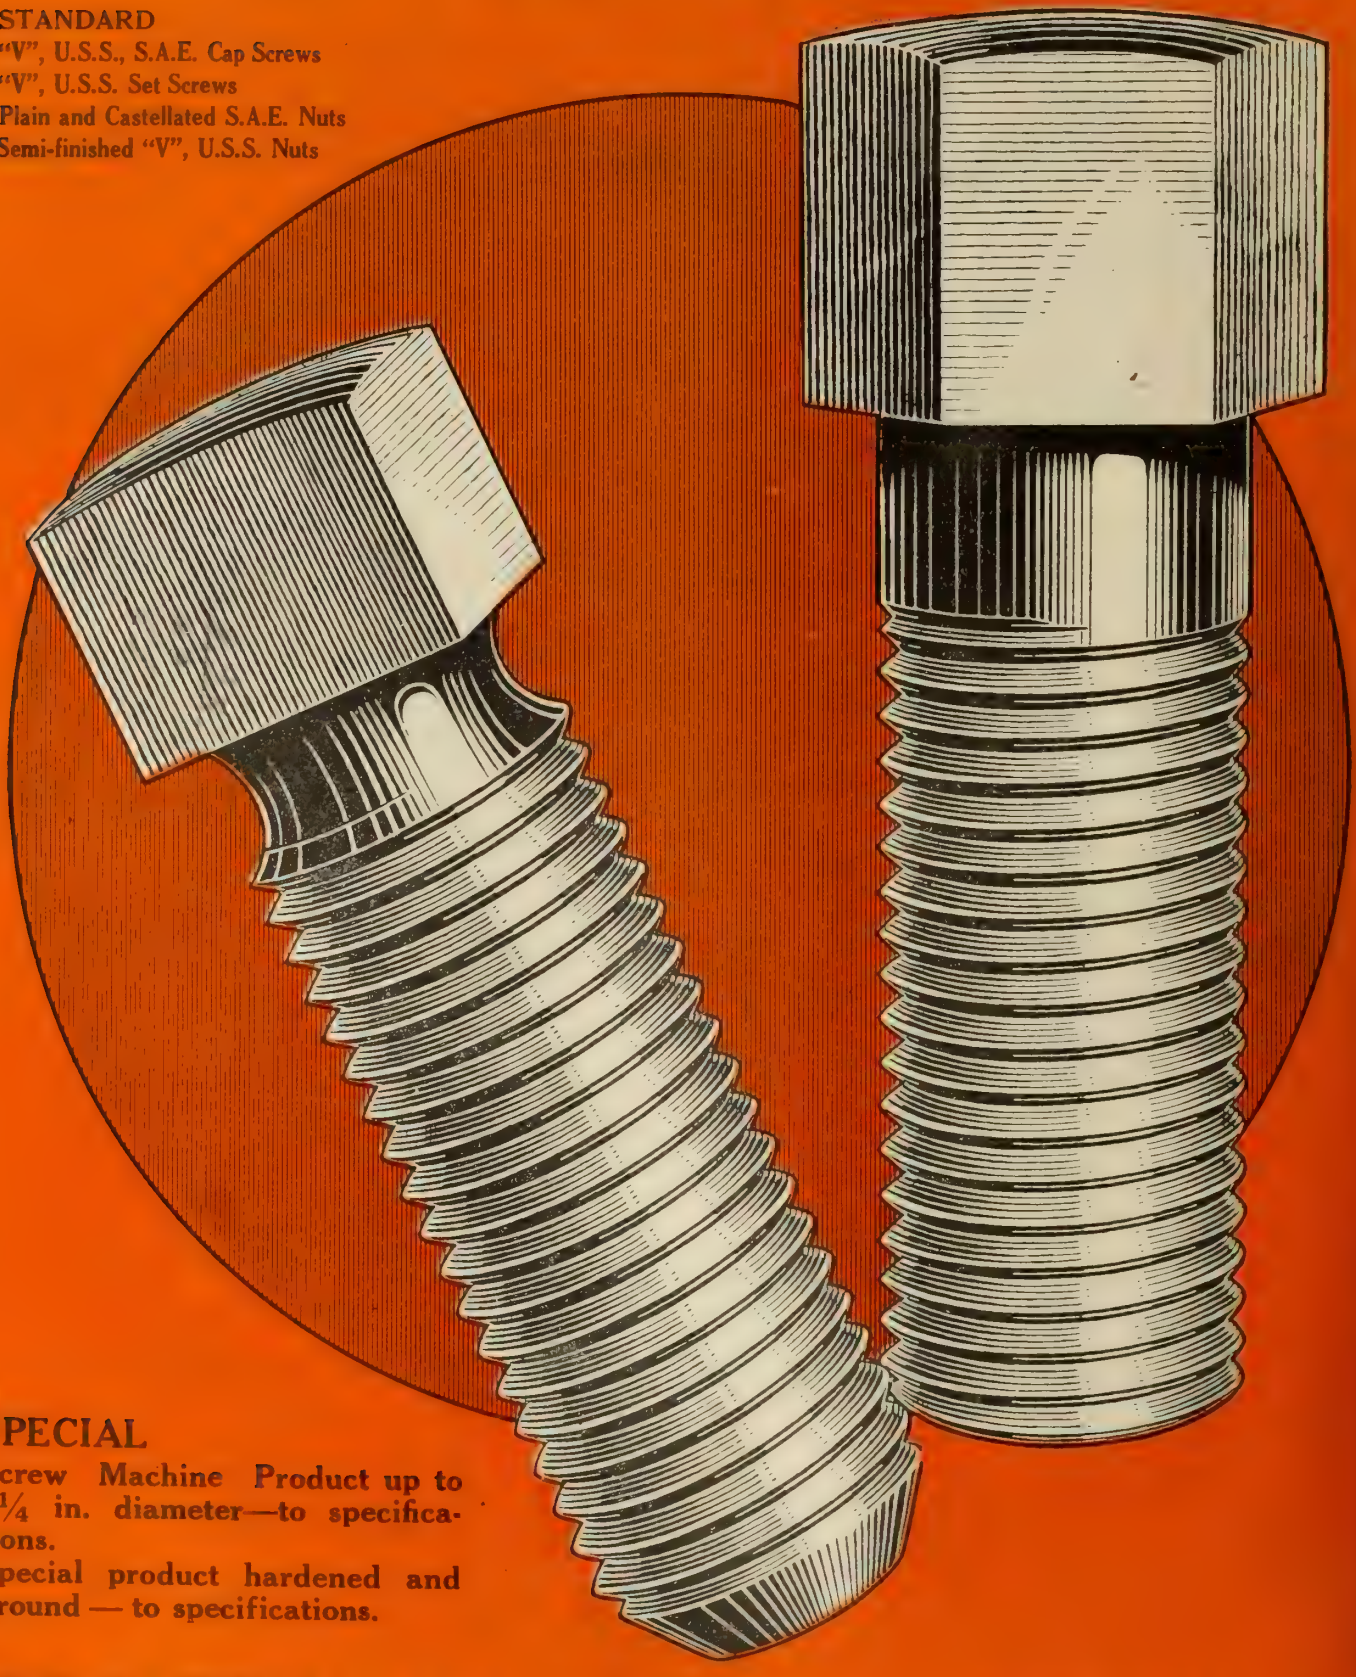
Metal furniture, frames, poles, handles, machine parts, pipe lines —these suggest just a few of the varied uses of this tubing.

Diameters range from one-fourth inch to three inches, and gauges from 24 to 11.

Standard Tubing can be supplied in several grades of finish, from a hot rolled finish to the highest grade of polish, such as is necessary before nickelplating.

It can be swaged to varying diameters in one piece, or can be bent to many different radii. Some automobile exhaust tubes have as many as five bends in them.

Standard Tubing is notable for its uniformity, smooth finish and trueness to diameter and gauge. It combines quality with economy.



We can give you expert advice on the use of Standard Tubing in your product. Your inquiry will have our careful attention.

J.B.&S.

THE GOOD JOB: *O. K. verified by tests and close inspection of work. No need to worry about this job.*

THE BAD JOB: *This job plainly shows trouble so steps are taken to seek the cause and effect a cure.*

THE DECEPTIVE JOB: *O. K. not verified by test. No special attention focused on work because of lack of complaints.*

Like a bad tooth that causes no pain

IT FREQUENTLY happens that the cleaning of work in process of manufacture is regarded as O.K. for the reason that no complaints have come to the attention of higher executives. Yet this type of job is likely to be poisoning the system of production.

Common factory ailments such as a high percentage of rejects after plating or japanning, or trouble in assembling parts, are often directly traceable to, but not charged up against, *improper cleaning.*

There have been many such instances where Oakite methods and materials have succeeded in doing a much better cleaning job than was formerly deemed possible. And this means that they have made it possible to clean the work perfectly, in less time, with less labor, and at less cost.

Will a critical examination of your cleaning method reveal that it is costing you *more than* (1) *you think it does* and *more than* (2) *it ought to?* The way to find out is to compare your methods with the best standards of practice.

Perhaps it would aid you in solving your problems for us to tell you what our experience has been in overcoming similar difficulties in a great many plants. Let us send one of our experienced men to see you.

It incurs no obligation to have a friendly talk with him about your cleaning problems. Find out what he can do. Out of his broad experience and ability you are sure to get some helpful ideas that will be worth while.

Drop us a postal card—it is a little thing to do but a big step in the right direction.

Rejects formerly ran 6% now 1/8 of 1%

Due to improper cleaning an auto plant used to run 6% rejects in the japanning room. By cleaning parts with Oakite materials rejects were cut to 1/8 of 1%, practically a perfect score.

SHEET METAL WORKING MACHINERY

BLISS

BLISS INCLINABLE POWER PRESSES.

Battery of "Bliss" Inclinable Presses in Operation

These presses combine convenience, durability and wide range of usefulness. They are built in many sizes. Weights, 750 to 10,000 lbs. Adapted for nearly every kind of blank cutting, perforating, forming and combination die work.

They take care of a large percentage of the operations required in the manufacture of cans, pieced tin ware, electrical goods, brass goods, trimmings, etc.

Write us your requirements, there is a size that just fits your special need.

ARMSTRONG

Safety Clamp Lathe Dogs

THIS Dog is so constructed as to combine a wide range of adjustment with the convenient features of the Clamp Dog and the Simplicity and Strength of the ordinary Lathe Dog.

It is specially adapted for use on finished work which would be liable to be damaged by the set screw of a common Lathe Dog.

A distinct advantage of this Dog is that it can be applied without removing work from centres.

ELIMINATE VALVE INEFFICIENCY

NEW AIR-TIGHT BLAST GATE
Light, Strong, Compact, Inexpensive, Quick-Acting. Threaded or Flanged connections.

Carlisle, Penna.
We are using your Blast Gate as an outlet valve on a starch tank. This tank contains a very heavy grade of starch—just liquid enough to flow. This heavy substance clogs the ordinary valve but your blast gate has, to date, given perfect satisfaction.
C. H. Masland & Sons, Inc.

Hundreds of former valve users have found the remedy by installing Rockwell New Air-Tight Blast Gates.

This wonderful control device has proved an ideal substitute for expensive, heavy, cumbersome and slow-acting gate and globe valves when used for:

Air and Gases of Various kinds

Blast furnace coal and lime dust
Counteracting back pressures
Distillation processes
Pulverized coal
Chemicals handled through pipes
Gas engine exhaust lines
Soot chutes
Starch

Present industrial conditions make it urgent that you investigate the economy and efficiency of this New Air-Tight Blast Gate. Ask our Canadian distributor for Circular 210-T.

Effective Cooperation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales. Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind. Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

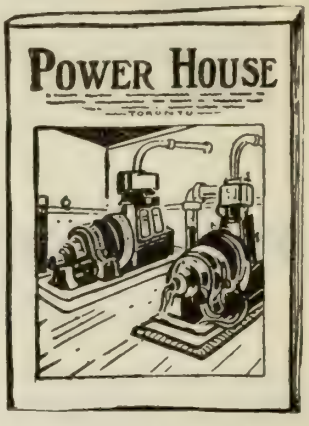
An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

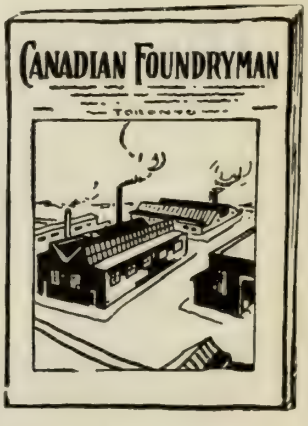
CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.



Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.



Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

What do you look for —in a Spring?

DO YOU look for quality — so high that the spring will function efficiently under all conditions; that it will "stand up" under the severest usage; that it will outlive several others in usefulness?

These are attributes long associated with RAYMOND SPRINGS and which owe their being to scientific heat treatment by experts and the facilities of our up-to-date plant.

There is a RAYMOND SPRING for every purpose.

Raymond Mfg. Co., Ltd.

Corry, Pa., U.S.A.

WHEN you buy Hoists—Buy the Wright High Speed.

It's the most reliable, speediest, safest and easiest operated, one-man hoist that you can get.

All steel construction with large overload c. pacity. Built in sizes from 1 to 10 tons. Investigate and be convinced.

We have the proof. Shall we send it?

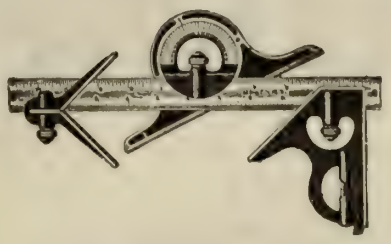
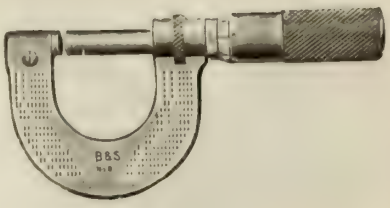
LISBON OHIO.



Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.



These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force can not replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments for machinery equipment.

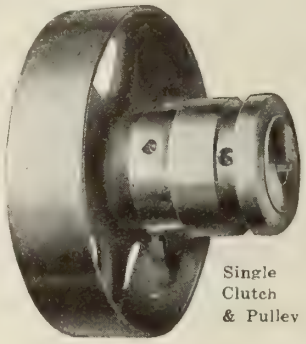
THE JOHNSON FRICTION CLUTCH

AS USED ON THE

"NEW" 12 IN. SUNDSTRAND MANUFACTURING LATHE



Progress in machine tool design demands a reliable and powerful friction clutch.

The Johnson Friction Clutch is proving of great value in machine tool designing.

Courtesy: The Rockford Tool Co., Rockford, Ill.

The main drive pulley is mounted on a No. 5 single clutch hub. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. The sliding sleeve is machined to act as a brake.

A feature of the Johnson Friction Clutch is the ease of application to particular machine requirements.

"Joy Shots" That Lead to Hell

By JUDGE EMILY F. MURPHY (*Janey Canuck*)

THIS IS the first of two articles in which Judge Murphy describes the menace that exists in Canada to-day in regard to the illegal traffic in narcotics. It gives actual facts from many Canadian cities and shows how the hypodermic needle is an even greater evil to combat than the opium pipe. The second of these articles will likely be in the July 15th issue.

Is Bootlegging a Passing Phase?

How common is bootlegging in Canada today? How do the members of the bootlegging profession carry on their business and what is their relationship to the officers of the law? These are two of the questions which are answered by A. Innes MacKenzie in a very colorful article describing the adventures, the fortunes and humorous rencontres of Canadian bootleggers from the Atlantic to the Pacific. Mr. MacKenzie writes whereof he knows, as he has spent several months studying this question and even associatting with many of the bootleggers themselves, in the interests of the readers of MACLEAN'S MAGAZINE.

Is the Canadian Flapper a Menace?

This is a question raised by Mrs. Gertrude S. Pringle in a startling article dealing with conditions as they too frequently exist in some Canadian centres. Extraordinary conditions are described by Mrs. Pringle, who is a thorough and conservative investigator. It is only too true, evidence regretfully shows, that some Canadian flappers are very much akin to their American sister who "parks her corsets and indulges in petting parties."

Quiet Gears

Why Tolerate Noise?

Use our efficient and durable Celeron or Rawhide Pinions

GEAR DATA FOR YOUR NOTE BOOK

Cut This Out—More Coming Later

SILENT PINIONS

From the Hamilton Gear & Machine Co., Toronto

NON-METALLIC PINIONS should be used wherever noisy gears would be objectionable. When well made they are really quiet. They have about the same strength as cast iron at slow speeds, and at high speeds they will carry more load than cast iron on account of their elasticity and smooth running. Rawhide will not stand oil or water. For such service use a pinion made in the same manner, but with Celeron instead of hide.

For best service and quietness make the face wide enough so that the metal mate does not touch the flanges of the pinion. When used on a motor add to the face the amount of the end play on the motor. Do not drive rawhide pinions by a set screw in one hub. Use preferably a key to distribute the load to both flanges and put less strain on the rivets. Flanges should always be made the full outside diameter of the pinion. Red brass is the most suitable material.

We carry a good stock of both celeron and rawhide of superior quality and can make very quick delivery on pinions, especially standard styles without hubs.

Remember—Our Non-Metallic Pinions are Quiet and Serviceable. We make the best quality and quickest delivery.

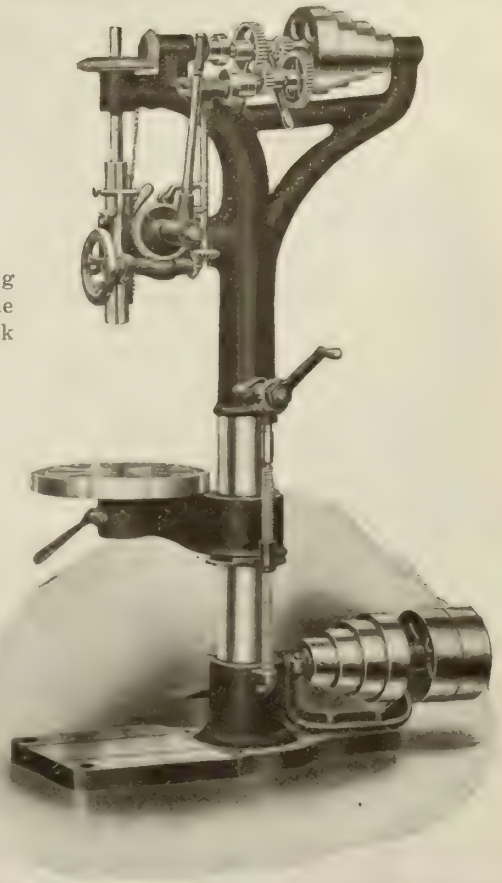
McDOUGALL



New and Improved 20-INCH DRILL

This new addition to the McDougall line is a profitable all-round drilling machine. Its parts are solid, simple and compact, the kind of machine to suit the demands of present day production. Equipped with back gears, power feed, automatic stop and quick return.

This machine will drill 1¼-inch holes in steel and 1½-inch holes in cast iron from solid metal and will bore up to several inches in cored holes.

With the power feed and automatic stop a number of them can be used in gangs, greatly reducing the cost of labor. Made without back gears or self-feed if desired; or with reverse motion. The reverse motion is simple and effective, requiring no extra belts.

Quality work at low cost of production follows where this machine is used. **Send for complete description.**

REX

A Complete line of BROWN & SHARPE MICROMETERS AT A LOW PRICE

To supply the need for highly accurate, inexpensive measuring instruments, we announce Rex Micrometers. The high Brown & Sharpe accuracy you have always known is now available to every shop at a low price.

Every Rex Micrometer, from No. 59, measuring 0 to 1 in., to No. 88, measuring 23 in. to 24 in., has a Clamp Ring which clamps the spindle and preserves the setting. A feature of these Rex Micrometers is the rectangular frame giving greater measuring capacity than frames of the circular type. The anvil, spindle, and other parts are similar to the regular Brown & Sharpe Micrometers, and means are provided for adjustment for wear of measuring surfaces and screw.

Rex Micrometers are furnished singly or in several different sets. They provide accurate, inexpensive measuring tools for every manufacturing requirement, from the first operation to the final inspection.

Learn about these high quality, low price instruments—send for descriptive circular showing the complete Rex line. Rex Micrometers are Brown & Sharpe Tools.

Stamping and Forging Sheet Metal in Power Presses

Development of Punch Press Has Attained a High Degree of Accuracy—Toggle Operated Blank Holder Prevents Wrinkling of Work While Drawing—Trimming Drop Forgings

NO CLASS of machinery engines or tools have helped more to develop the metal working industry to the present high standard of efficiency and production than the stamping and forging presses and special equipment used in manufacturing all parts and articles made from sheet metal of all description.

The start in this direction, on a commercial basis, was made about 1867, when small foot operated pendulum presses were used for the purpose of plain blanking, perforating and forming dies. The demand soon came for increased output and power presses were constructed, giving greater accuracy to the work produced and greatly reducing the maintenance cost on the puhches, and dies. In a short time the use of power presses had become more general, the field for the use of these having been greatly increased by the development and designing of combination dies and other tools which permitted of rapidly transforming flat sheets into finished or partially finished shapes. The progress in recent years in working sheet metal into commercial articles has been rapid and has covered the stamping not only of the lighter gauge metals by the cold process, but also sheet metals as heavy as one half inch and as large as the frame of an auto truck, and the end of a steel freight car without heating the metal. In fact from a very crude beginning in 1867, this art has developed into such an elaborate science, so much, that the power press with its many sided applications has to-day become recognized as an absolute necessity in plants where sheet metal is used, and they are directly responsible for making it possible to sell automobiles, and other utilities at their present price.

In former years the machines used in working sheet metal were exceedingly simple but the constant demand for cheaper and more uniform products has developed mechanical presses which now actually stamp many articles and parts of light and heavy gauge, which formerly had to be made from castings and forgings, such as side frames, cross-members, rear axle housings, front axles, engine-pans, steering wheels, timing gears, cases, and covers. Generator and starting motor frames, wheel hubs, wheels, rims, spring brackets, brake drums, connecting rods, universal joint casings, radiator shells, etc. Particularly interesting are the presses and tools which have been developed for stamping and forming automobile bodies, fenders, cowls, radiators, shells, etc. In forming the above mentioned shapes, it is necessary to hold the flat sheet under sufficient pressure to prevent same from wrinkling and in the earlier days when we had but single acting presses, it was necessary to apply enormous springs, against the pressure plate to accomplish this.

Experience, however, especially on large forming dies, has shown that the spring pressure device was not reliable not giving uniform results and limiting the depth of draw, also in stretching the metal. In the new type of presses used for the above mentioned parts, we eliminated the spring pressure device and are operating the pressure plate, or as known by all, the blankholder, by a simple arrangement of toggle links, giving a positive and uniform pressure, no matter if the draw is 1in. deep or 20in. deep. Besides this, it eliminates the pressure against the crankshaft due to the resistance of the springs, as the toggle links are operated directly

Cuts 1 and 2 by courtesy of the E. W. Bliss Co. Cut 3 through courtesy of Parish & Bingham of Cleveland, Ohio.

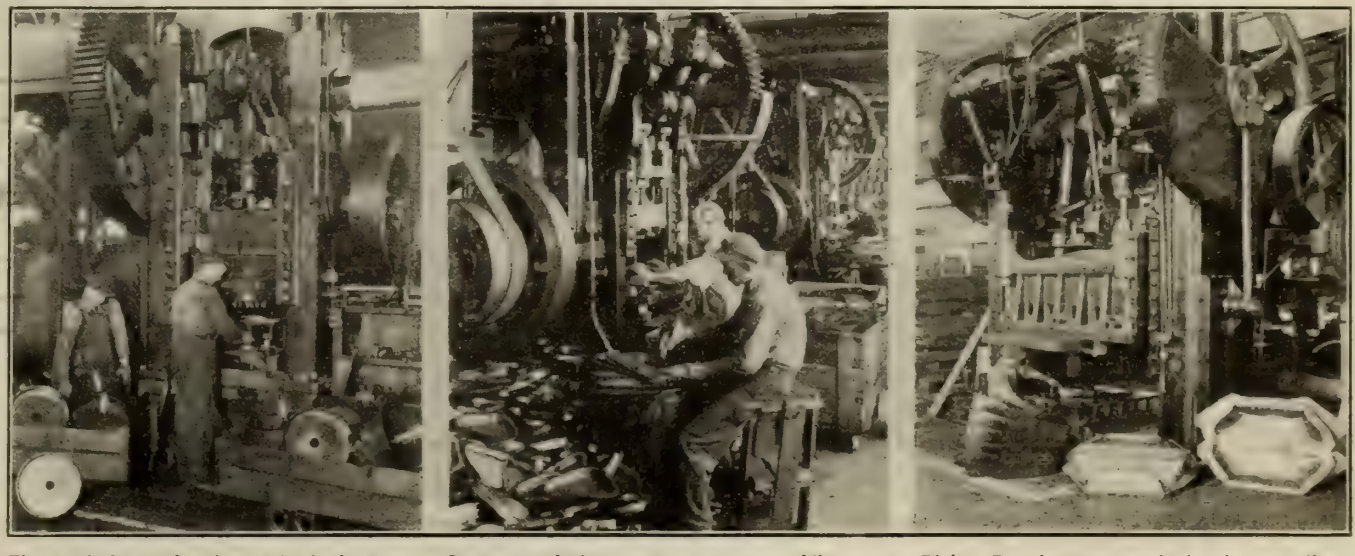

Fig. 1.—Left: Perforating 16 in. brake drums. .Centre: Producing covers for automobile gears. Right: Drawing two cowls in the one die.

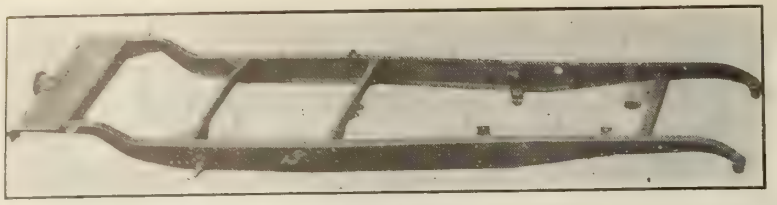

Fig. 3.—Chassis built up of pressed steel parts.

from the main gears. It might be well to mention that due to the toggle links, being operated by both main gears, it insures double safety against the breaking of any of the toggle links, or the stopping of the press, as the construction is such that either side of the driving parts is strong enough to operate the entire blankholder motion. This particular mechanism is controlled and covered by patents which are held by the E. W. Bliss Co. It will also be of interest to know that mechanical presses have practically eliminated the hydraulic presses in forming side rails. About six years ago, the first mechanical press was built to produce a right and left hand Ford side rail. This press was built with a single acting motion operating the slide, carrying the die, and forming the metal around the punch. The latest type of these presses has a double acting motion, one for operating the punch and one for operating the blankholder. The object of the blankholder is to clamp the blank securely against the punch so as to keep it flat while forming up the sides. This is very desirable, as it makes it easier to fit brackets, stephangers, and cross-members. One of these presses is turning out an average 300 side rails an hour. At present presses are built weighing beyond 200 tons, to form side rails up to 21 feet long and up to ⅜in. thick.

Another interesting press development is going on in the drop forging line, especially in small and intricate forgings, such as levers, bell-cranks steering knuckles, small wheel hubs, gear blanks, etc. For years they have been made in ponderous drop and steam-hammers. With the new process of forging the parts in power presses this cost is cut down more than 50 per cent. and the products are better. We expect in a short time to see forgings weighing two pounds made from a two-pound slug and eliminating the flash altogether. Powerful knuckle joint presses are already in operation sizing and squeezing forgings.

The illustration herewith show several operations performed on large toggle draw presses in plants making parts for automobiles. At the left of Fig. 1 is seen a No 70½ straight side press producing 16in. brake drums. The operation consists of piercing 12 holes ½in. dia. in the drum. The material is hot pressed steel 3/16in. gauge. The production rate is 5,000 per ten hours. This press is likewise used for forming hub flanges from ½in. stock, hot pressed steel at rate of 4,500 per ten hours.

In the centre is shown a No. 3½-B toggle drawing press cutting and drawing covers for automobile gears from hot-rolled steel .049in. thick and 13-3/16 in. wide. In nine hours 2,500 pieces are produced. At the rear is shown another press of the same description working on the first draw for automotor water jackets. The blanks are 14in. dia. being of copper .037in. thick. The rate of production is 4,000 per 9½ hours.

An interesting press forming operation is shown to the right of Fig. 1. Previous to making these cowls in the method here illustrated they had been made singly but difficulty was always experienced in obtaining products free from wrinkles. The adoption of the duplex die solved the problem as the symmetrical form of the draw when two cowls are produced back to back provides an evenly distributed draw to the sheet and wrinkles are reduced to a minimum.

To the left of Fig. 2 is shown an improved method of producing fenders. Two of these are now made at the same time. The great difficulty of holding two separate blanks at the same time is met perfectly in this toggle press by fine and accurate adjustment of press ram and gauges. Finished product shows no signs of buckles or stretcher strains.

To the right of Fig. 2 is shown an operation of trimming a crank shaft after the forging has been produced in the adjoining press.

A good example of the class of product now being produced on power presses is illustrated in Fig. 3. This chassis is made up of different parts that have previously been produced in power forming, drawing and drop forge presses.

THE ROTASCOPE

The National Physical Laboratory, which was established near London by the British Government, has produced quite a number of scientific instruments of the highest value. One of these was recently shown at a scientific exhibition in London. Its purpose is to render a rotating object continuously visible while it appears to be at rest. The method adopted is different from that of illuminating the object by a series of brief flashes of light. The principle made use of is a property of reflection from a smooth surface which is rotated round an axis parallel to the surface and in line with the axis of the object. When this reflecting surface is rotated at half the speed of the object itself, the image in the reflecting surface appears stationary. This instrument is expected to prove useful for measuring speed and for studying the phenomena of vibration and strain in rotating objects.

IMPROVED HAND DRILL

The ordinary small hand-operated drill is widely used on account of its convenience, but it has the drawback that it is not quite so accurate in its work as a proper machine drill. With the object of getting over this disability a British firm of tool makers has designed a new type of hand drill which does as good work as the high grade machine drill, while retaining all the simplicity of the hand-drill. Both a high and a low speed are provided; and another very useful feature is the automatic action by which the drill is fed forward as it proceeds through the work. The work table of this little machine can be swung to any angle and also rotated round a vertical column, so that the drilling of holes at any angle is a comparatively easy matter. The machine is designed for hard work and can drill holes up to one inch in diameter. The height of the machine is only forty inches and it is made throughout with exactly the same minute care as is expended on the best British machine tools.

Fig. 2.—Left; producing two fenders at once. Right; trimming crankshaft after forging.

Value of Keeping Tools and Product Clean

Cleanliness An Important Part of Plant Management—Cleaning Medium Should Not Be Subject to Fire Hazard—Keep Bearing Surfaces Clean—Use of Chemical Compounds

By J. H. RODGERS

WHILE passing through a small plant recently the writer overheard the following remark: "There is an old proverb that says—'Cleanliness is next to Godliness,' but here it seems next to impossible."

The statement was made by the shop foreman and was occasioned by the unsanitary condition of the floor and the general untidy appearance of the whole establishment. One could not help but concur with the utterance of the foreman as the expression was particularly fitting in this instance. The floor was blotted in many places with patches of caked oil and dirt accumulated beneath each hanger of the main line shaft and everywhere was displayed some evidence of about 100 per cent. neglect, in the matter of clean and healthy surroundings. Men operating presses, "enjoying" the habit of the use of tobacco, would turn their heads, without any apparent consideration for their immediate neighbor or the product of the shop, and expectorate on the floor. Some would take the additional precaution of selecting a dark, unseen corner near the wall or base of the machine to deposit the fruits of their jaw labor. Of the two, the former must be given preference, as there is a remote possibility that the refuse will be gathered up and removed, while in the latter case the accumulation of filth provides an ideal nesting place for myriads of germs that eventually seek out and prey on the health of those working in the shop.

Degree of Cleanliness

What is true of plant condition is equally true in respect to the product made in the shop. Cleanliness must continue to be a dominant factor of plant management. It should be understood, however, that varying degrees of cleanliness will prevail in different establishments, based on the quality and character of the product manufactured, as it could not be expected that a brickyard would have the same standard of neatness and appearance as the assembly department of a high-grade watch-making factory. The range of manufacture is so extensive that it would not be permissible to cover this subject in its entirety so we will confine our remarks to the question as affecting metal working plants.

Cleaning of Metal Parts

The rapid development of the automotive industry has given impetus to the cleaning of parts during the process of manufacture, and it has now reached the stage when progressive executives include it among the principal factors of the production problem. The extensive use of turret lathes and automatic machines, using large quantities of lubricating oils and compounds in the machining operations, has necessitated some economic method of removing and reclaiming the oils for further service. This is essential for two prime reasons: first, the economic feature of oil conservation, and second, the advisability of keeping a product clean.

Method of Cleaning

The comparative high price of oils to-day prohibits undue waste of consumption and the washing of oily pieces as they come from the machine is very necessary. The method of cleaning may take one of many forms. The practice of using soap and water has long been discarded as an efficient means of cleaning metal parts. Alkalies in a variety of forms have been used in different ways, but in removing dirt and oil the surfaces were left covered with an insoluble soapy substance that was often difficult to remove and giving to the product a touch that was far from pleasant.

Use of Gasoline

Gasoline has been widely used as a cleaning medium, yet while serving its purpose in its main requirements, has highly objectionable features from a hazardous standpoint. The inflammable nature of gasoline detracts greatly from its otherwise beneficial characteristics. The relatively rapid evaporation of gasoline is a point in its favor, when judged as a cleaner, as the parts soon have a dry clean surface, free from the clammy, sticky touch generally associated with oil coated metal. On the other hand, the evaporation of the gasoline, when the same is open to the atmosphere, produces a condition that is not only dangerous as a fire hazard, but injurious to the health of the workmen. The air becomes so saturated with the fumes that the men suffer from headaches and temporary dizziness.

Specific Instance

On one occasion the writer was working in a plant where gasoline was used for cleaning the parts as they came from the turret lathe. The can when not in use was kept covered, but when dipping the pieces the top was removed. On this particular occasion, the cover was off and without a moments warning a flame one ft. in diameter rose to the ceiling. The operator endeavored to blow out the fire, singeing his hair and eyebrows in the effort but with no success. Another worker grabbed the lid and dashed it on the can, thus smothering the flame and arresting a stampede about to take place by the other employees. It was never definitely determined just what ignited the gasoline, but it is supposed the fire originated from a spark from an abrasive wheel, there being a universal grinder operating close by at the time.

Chemical Solutions

Chemical preparations are now largely used for removing dirt, grease and oil from metal and other surfaces and have proved highly satisfactory both from the viewpoint of efficiency and economy. The handling of a machine part that has been thoroughly cleaned of all foreign substances used in previous machining operations, gives to the workman a sense of cleanliness that seems to influence his every action, and he invariably finds greater pleasure in doing work that might otherwise be objectionable.

When metal parts are to be painted after assembly it is especially desirable that they be thoroughly cleaned with a solution that will show no tendency to develop rust spots upon the metal surface.

Keeping Bearing Surfaces Clean

The value of keeping a product clean is particularly noticeable in the case of machine tool operating on a production basis. The essential part of metal turning is to utilize the maximum amount of power delivered to the tool for the actual cutting of the stock. Any excessive power used in overcoming friction of sliding or revolving surfaces may be considered as so much waste. Every emphasis should be placed on machine operations on the subject of keeping their tools clean and suggesting regular periods when systematic cleaning shall be performed—and seeing that this work is carried out. In mentioning this the writer is reminded of the operation of a large lathe in the machining of heavy cast iron equipment. The dust and fine particles will gradually work their way into bearings and ways of the bed and cross slide, and becoming mixed with the oil form into a sticky, adhesive film, entailing extreme physical effort when moving saddle by hand, and absorbing unnecessary power when cutting is in progress. The cleaning of the ways from time to time and re-oiling (not too freely) resulted in obtaining greater production from the machine. The large bearings in the headstock were washed out once a week and this likewise proved advantageous. This shop now makes a practice of overlooking all tools and provide every means of protecting oil holes and bearing surfaces of all machines and transmission equipment, giving bearings a thorough cleaning, at least once a month, using a suitable chemical preparation for the purpose.

The practice of keeping work clean is nowhere more emphasized than in such

(Continued on page 34)

Reducing Costs By Means of the Planer

Variable Cutting Speeds First Step in Reduction of Costs—Feed Motion Should Have Ample Range for Both Stock Removing and Broad Finish Scraping—Examples of Work Completed

By J. G. STIRK

THIS problem is not one of the easiest to approach. It is not a case of the hammer, chisel and scraper versus planer, or there is no problem. It is not a case of the milling machine versus the planer, or the matter is too readily solved to be called a problem. There are jobs for which the milling machine is the obvious tool, whereas there are others where the planing machine has indisputable advantages.

The question at issue in the mind of the writer, is one of efficiency in the use of the planer. In other words there is planing, and there is planing. Are you getting the best possible service in your planing shops, and are your total production costs greater or less because of the way in which that department is equipped, organized or operated? Now, that is quite a long question, and quite a number of suggestions may be made to enable a specific answer to be returned.

First then, about the machines themselves. Single cutting speed machines have their uses. If a machine is to operate on the same job day in and day out, year in and year out, it should be easy to determine the most suitable cutting speed, and fixing on that, save both prime cost and upkeep of all unnecessary additions in the way of variable speed mechanisms. There are however the thousand and one instances where no such uniformity and continuity can be achieved, and where a real loss is incurred through inability to change speed when the fixed speed is unsuitable. If therefore, yours is one of those thousand and one cases, specify variable cutting speeds on your additional planer, or (the writer confesses himself an interested party) if you do not need an additional machine, pull out one or more of the existing machines and replace with modern variable cut planers as a first step to reducing planing costs.

Possibly a range of three or four speeds, say, 24, 36, 48, f.p.m. will cover all your requirements. In that event a belt driven planer with belt or motor driven countershaft may fill your bill. In many shops however a wide variation by the finest gradations is a vital necessity, and in such cases a direct coupled reversing motor is undoubtedly the proper thing. Equally undoubtedly some form of Ward Lennard (motor generator) drive is, to my mind, infinitely superior to any single reversing motor system. In the first place the latter can only be used where direct current is available. In the second, third, fourth and fifth place, the practicable maximum ratio of return to cutting speed is 8 to 1, against 3 to 1. There are 12 to 18 intermediate speeds, the switch gear is simple and there is a corresponding freedom from operating troubles and costly breakdowns. This system has had a great vogue in Europe and the best known examples are the Lancashire planer drive, (patented in Great Britain) and the Stirk split field drive (patented in Great Britain, Canada, United States, and many other countries).

A further advantage of these drives is the facility with which the cutting speed may be accelerated. Every shop has planing jobs where between the surfaces to be planed are intervening spaces, which under these systems can be covered at return speed. In other instances it is desirable to speed up in metal, and possibly retard again before the tool leaves the job. The Woodward and Powell accelerating cut planer is the only belt driven machine which gives even one of these features, whereas all are embodied in the Lancashire or Stirk drives.

Mechanical Details

Reverting to the mechanical details of the planer you will require a good reliable feed motion which will provide ample range for both stock removing, and broad finish scraping. You will require such strength of gearing as will stand up to the heaviest duty, and such accuracy as will ensure that wherever possible your product is finished when it comes off the planer table, especially if the cutting is of an intermittent character; but in any case, you will be well advised to specify in your new machines steel driving gears, and if possible of the "Keyless" variety. It is in this way that continuous service is obtained and costs correspondingly reduced.

So much (without in any way exhausting the subject) regarding the bare machine itself. Closely allied as cost reducing details are first, the selection of treatment of tool steel, second, gang planing, and third, special methods of setting and fixing the work.

As to No. 1, sufficient is written every month on this subject to render unnecessary the addition of a single word. Re-

Author came for a hurried visit to Canada, and while in Toronto, we requested him to give us something on planer practice. Mr. Stirk is general manager of the J. G. Stirk Planer Co., Halifax, England, and is an authority, not only in production work, but planer design.

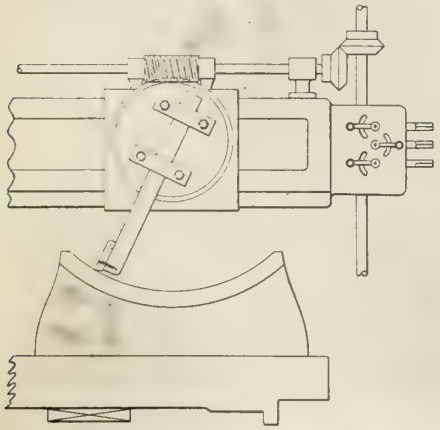

Fig. 3.—Showing method of planing out the radial segments of boiler saddles.

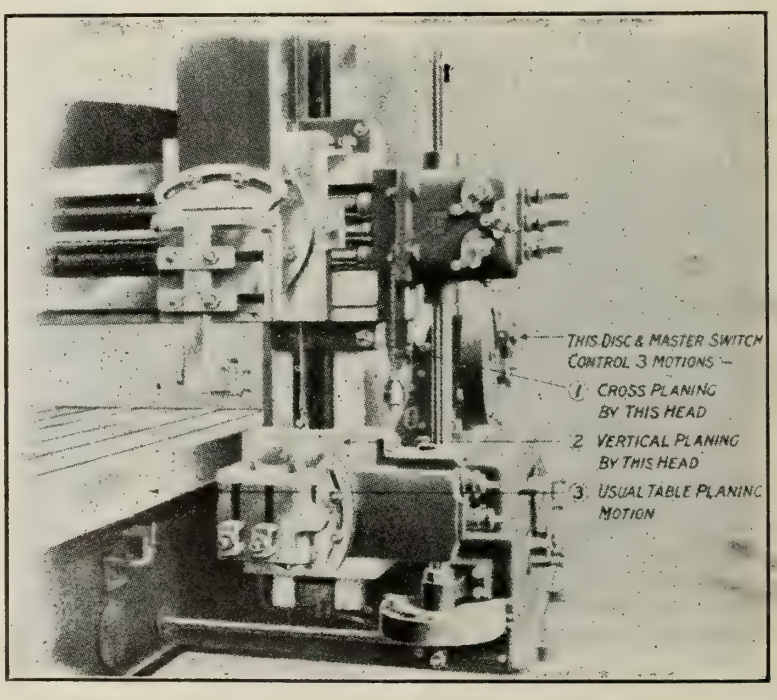

Fig. 1—Showing double ended pendant switch.

garding No. 2 this seems self evidently advantageous, but very often the capacity of existing planers precludes the possibility of machining more than one piece at once however simple the operation may be. Remember therefore the next time to look into the possibilities in this direction.

The writer recently saw both at the Great Western Railway Works at Swindon, England, and the London and North Western Railway Works at Crewe, England, crank webs being planed in large batches, and at a saving of 20 per cent. to 25 per cent. over the previous policy of machining only a few at once. This saving however was partly due to the split field drive named above.

Most remarkable reductions in costs can be achieved by special fixtures, etc. It is notorious that many planers do not actually run more than 25 or 30 per cent. of the time for which the operator is drawing his wage. As the interest on the investment is going on all the time this represents deplorable losses. The first step to cut these losses is to provide power traverses to the heads on machines of substantial size so that the operator is not expending time and energy moving the heads by a process akin to performing on that other obsolete instrument, the barrel organ. Moreover the power traverses should be readily controlled, and Fig. 1 shows a double ended pendant switch which enables the tool to be moved horizontally or vertically by as little as 1-16 in. Being portable, the switch may be held in the hand when the operator leans over to see into an awkward corner of the job. This is in marked contrast to a power traverse motion actuated by a lever in a fixed position.

Having eliminated waste of time in movement of the heads, the next thing is to consider the loss through the machine standing whilst the table is being loaded. In many instances this is an unavoidable loss and can only be reduced, not by installing this or that make of planer, but by engaging the best and most intelligent operator. There are however many other cases where the dimensions of the job are modest and the quantity great, which lend themselves to a combination of gang planing and special fixtures in a peculiar degree. Specific examples are greatly superior to vague generalizations and the writer will therefore describe a few jobs as performed by his own friends in English shops.

Some English Methods

1. Planing electric motor magnet yokes. The Electric Construction Co., Wolverhampton; Crompton and Co., Chelmsford, and some other firms plane both feet and (where yoke is split) the joint in the following manner. Only the two side heads are employed, and the yokes placed on the side with the faces to be planed outwards. They are not, however, directly bolted to the table of the planer, but to a false table approximately equal in size to the regular table and fixed thereon complete with its load of two rows of motor yokes, one row down each side. There are two of these false tables, and a competent assistant is loading one while the machine and operator are at work on the other. The planer is thus kept running practically continuously, and costs of production reduced to an amazing extent. The machines in question are fitted with stirk drives and full advantage is taken of the acceleration to save time between surfaces, the actual lengths of surface machined being quite short. Maximum return speeds are of course employed, say 180 f. p. m. on 78 in. wide machine, and the users declare that two machines so equipped produce work equal in volume to 10 machines previously used—a reduction in costs of 80 per cent.

A similar though not identical scheme is in use by the leading gas engineers, Messrs. Cockey and Co, Fromel, Messrs. Dempster and Co., Manchester, and Messrs. Drakes, Halifax, for planing tank plates. For this work 6 ft. by 16 ft. planers are made with the table in two half lengths which may be cottered together when required or run separately. While the pile of plates on table No. 1 are being planed, a similar pile is being set on No. 2 table at the rear. On completion of the first batch No. 1 table is run up against No. 2, the cotters inserted, and No. 2 table drawn into working position. The cotters are now withdrawn, and No. 1 table left at the front end of the bed to be duly loaded whilst actual cutting proceeds on No. 2. The process is repeated as each set is completed, and as with the motor yokes, something closely approaching continuous operation is achieved with corresponding reduction in costs.

Another example of special fixtures is a revolving table used by Messrs. Kitson and Co., Leeds, England, on locomotive cylinder work, whereby facings at right angles may be machined at one setting. The same end is achieved by the Midland Railway Co., Derby, by using a Hiloplane embodying automatic cross and vertical planing. By this means planing in three directions is accomplished at one setting.

Fig. 2 shows a very striking example of the adaptability of the Hiloplane, for not only are cross and vertical planing motions available, controlled by the main stroke disc but the automatic reverse may be applied to any of the motions having a self-acting feed and the illustration shows the slotting of a keyway in a large spur wheel in an emergency. This is not an outstanding example of low cost in actual time taken for the job. This was undoubtedly considerably in excess of the time which would have been taken on a standard key-seating machine, or even a good slotter, but insofar as it was an odd job not likely to be repeated, investment costs were saved through the adaptability of this particular machine.

Messrs. Armstrong Whitworth and

Overcoming Heavy Costs of Belt Maintenance

Transmission Problems Should be in Charge of Competent Man —Inspection Should be Made Regularly—Importance of Proper Alignment—Lacing of Joints Should Be Carefully Performed

By J. H. RODGERS

BELT dressings are of two types: those intended to prevent slippage, and those used to preserve the fibre of the leather. The most common examples of the first class are perhaps soap or powdered rosin, which the average mechanic uses freely. Dressings in this class are often made of some sticky material dissolved in any oily solvent and scented to conceal their odor. Black belt dressings often have tar or asphalt for the sticky material, kerosene or turpentine for the solvent, and oil of mirbane or citronelle for the odorous constituent. Belts treated with such dressings quickly become coated over and soon both belt and pulley are glazed with a dirty surface that slips worse than before. Selecting a dressing for belts is as important as the selecting of lubricating oils for machinery. Some simple test should be used to see that they do not contain any harmful ingredients. In some fluid dressings naptha or gasolene is used. These are initial preservatives of leather and their presence often indicates other harmful ingredients which are kept in liquid form by them. Since volatile oils evaporate rapidly, dressings containing them have to be applied very often to secure any result.

Destructive Practice

When surface dressing—or as it is often called, the "belt stick"—is freely used, it is not uncommon to see pulleys in the condition shown at F, Fig. 6, where large patches of the dressing cling to the face. As said before a belt derives its power from frictional contact with the pulleys and while the pull from a well "dressed" belt may seem better, the general efficiency has not been increased. This may be made more clear when one realizes the air pockets that must be formed between the patches on the pulley surface. To this must be added the pull required when the belt is leaving the pulley. A stamp may be easily placed on an envelope but some action is required in its removal. At your next opportunity notice a drive of this description and listen to the noise when starting or stopping. Just like pulling a porous plaster from your back.

Detection of Naptha or Gasolene

Naptha or gasolene can readily be detected by putting a few drops of the dressing in the palm of the hand and rubbing it until the mixture warms slightly—the odor will be easily noticeable. If the dressing contains oils of a gummy or drying nature, harmful to the belt, they can be detected by putting a few drops on window glass. If after it is left in a dry hot place for a few days, it feels sticky, or if it becomes dry and forms a crust it would be apt to do the same thing on a belt and should not be used.

Another simple test consists in taking a piece of new leather preferably from the belt on which the dressing is to be used, putting a few drops of the dressing on the leather and laying it on the engine cylinder or steam chest until quite warm. Note the time required for the dressing to penetrate the leather. If the surface is left clean and feels sticky, it indicates that harmful ingredients are present. If all of the sample penetrates the leather, leaving no residue, and the spot where the dressing was applied feels soft and velvety, it indicates a good dressing. Common examples of the second type of dressing —intended to preserve the leather—are neatsfoot or Brockton oil, castor oil, and dubbib (a mixture of cod-oil and tallow). These, properly used, will keep leather belts thoroughly pliable, mellow and sufficiently greasy to have the maximum co-efficient of friction. These dressings penetrate the leather and depend for their effectiveness on their action on the leather, while the sticky dressings remain largely on the surface.

The use of sticky dressings often results in pulling the laps apart and peeling off the grain of the leather because of sticking of belt to pulley by the dressing; overstrain of leather due to the use of belts of inadequate size, made to carry overloads by use of such dressings; uneven frictional contact and belt strain due to accumulation of lumps of dressing and dirt on pulleys and belt —actual damage to the leather fibre from components of dressing and from excessive slippage. When a leather belt is slipping badly, because it is not tight enough or because of sudden overload, it may be permissible to use a little sticky dressing. For the continued use of sticky dressings with leather belts there can be no excuse and with the right belt no need. Practically all belt dressings of the second class cause a slight temporary increase of slippage at the time of application—the amount of this depending on the amount of dressing used and on the rapidity with which it is absorbed.

The best time to apply dressing is when the belt is idle and can stand for some time so that the dressing can penetrate into the leather. Penetration is assisted by warming the dressing also. When it is not practicable to apply dressing to the belt while idle, a piece of burlap or waste covered with dressing may be held to each surface of the belt while running and a thin film of dressing be deposited in this way on the leather. The fundamental requirement is to have a clean leather surface to which to apply the dressing. It is worse than useless to put dressing on a belt already covered with dressing, or with dirt or oil. Therefore, remove all excess dirt by means of some form of scraper. A sharp-edged block answers the purpose very well. Then, if necessary, scrub with naptha or kerosene but whether by this or some other method, be sure of a leather surface that you can recognize as leather. Put a little

dressing on the driving surface, and more on the surface away from the pulley. A proper dressing will gradually work its way through the leather, and give the driving surface the necessary lubrication, causing it to have that mellow feel, readily recognized by the expert belt man. Probably the best way of doing this is to rub the belt all over with a piece of burlap covered with the dressing, having steadily in mind that too much dressing is apt to be more harmful than too little. No free grease should be apparent on the driving side of the belt after the dressing has been applied.

How To Treat New Belts

Mechanical tests show that the ordinary new belt will not carry the same load as it will after a few weeks service, by from 10 to 20%. It follows that on new belting a good light coat of dressing should be applied in the manner sugested above—before installing. Repetition at frequent intervals for the first few weeks would help, too. Remember that dressing is not put on the belt so that it may stick the belt to the pulley and thus make it pull more. It is put on so that by entering the leather fibres it may toughen them, lubricate them, and thus give longer life to the belt. Whenever the leather seems dry, harsh, tinny, does not have the right mellow feel—you may be sure dressing should be used.

Another important factor in belt economy is cleanliness, first of belt and then of pulley. A clean, soft hand will not slip easily even on smooth glass or polished wood. Leather was once skin, and smooth, clean leather will not slip easily on a smooth, bright pulley surface. Belt surface should be clean, smooth, level and comparatively dry. Tests have shown that the coefficient of friction (on iron and steel pulleys) is: .56 when dry, .36 when wet, .23 when greasy, .15 when oily. Therefore it is very important that both belt and pulley be kept as dry and clean as possible.

Too much grease is injurious to leather. Mineral oils in particular rot leather rather rapidly, and where belting is liable to become soaked with oil, mechanical means should be taken to keep the oil from the belt. Where mechanical protection is impossible, the belt should be removed from time to time and the oil extracted with some solvent such as naphtha or carbon tetrachloride.

Packing the belt in dry sawdust or shavings will sometimes answer the purpose. If it is impossible to remove the belt, wiping on the pulleys with a dry cloth or waste will help. Machine oil, in addition to its tendency to rot leather, when present in excess gives a very poor friction surface, as shown in the table preceding. Too much oil will penetrate the belt and affect the adhesive quality of the ordinary cement used in gluing belts together. Frequently, from this or other causes laps start up at the points, a result sometimes due to running belting in the wrong direction.

Direction of Travel

Another point that comes under discussion in connection with leather belts is that of the spliced joints, and their relation to the direction of travel. It is quite evident that the thin edge of the lap may show signs of parting after a period of service. For this reason some men contend that the belt should be run with the splice as shown at B, Fig 1. On this principle the action of the pulley will aid in keeping the thin edge down to its place. On the other hand, some belt men say that the action of the air on the belt surface when in motion tends to lift the edge from its place. As this air action is greatest when the joint is passing around the pulley it would appear that the subject is open to discussion. However, as slow running belts are not subjected to excessive air action it might be said that the method shown at B would be best, and that at A best suited for high speed belts. Irrespective of the advantages claimed for either method, the entire question seems to be one of careful attention in the matter of repairs and maintenance so that faults may be remedied as soon as they are observed.

Avoid Small Pulleys

In double or three ply belts these splices can be run to meet both conditions as shown. In the use of double or triple belts for heavy power drives, care should be taken to use pulleys as large as possible, consistent with speed requirements, as effective heavy drivers are impossible on pulleys of smaller diameter. This is quite clear when we consider the lack of flexibility of the heavier belts. Running over small pulleys also tends to create a fault as shown at G, Fig 1, when the ply of the belt may be losened.

A condition that sometimes arises in the case of old style lathes is that shown at Fig 9 where the belt will jump the flange and get caught in the gears. A guard will often eliminate this trouble.

Remember that because shafting was in line once it does not necessarily remain so indefinitely, and regular attention to this point will result in a large saving of time, trouble and power. Light machines, especially when not firmly fixed to the floor, are apt to get out of line a little. This misalignment is difficult to detect and always results in uneven belt strain, excessive slip and reduced delivered power.

The Mule Drive

Another drive that is occasionally used is that illustrated in Fig 8. This is known as the mule drive and is adopted where a machine is to be operated at right angles to the line shaft and where a quarter turn drive is not permissible. In the mule drive the connected shafts usually lie in the same horizontal plane, invariably at right angles, where the prolongation of the counter shaft would intersect the main shaft. The intermediate pulleys revolve in a horizontal direction on a vertical shaft. When it is desired to run the belt in either direction it is advisable to have the two main pulleys of the same diameter. Collars are necessary on the vertical shaft to support the pulleys. One bad feature in a mule drive where the load is a fluctuating one, is the tendency of the belt to run off the mule on the slack side. It is preferable to have the pull come in the lower side, but in either case the slack side should be provided with a guide pulley C, carried in a bracket B fixed to the mule shaft. This will aid in supporting the belt when the load is on the machine.

Proper Position of Ladder

When placing a belt on the pulleys it should first be located on the "dead" or driven pulley, as shown in Fig. 10, the actual running on of the belt being done on the driving pulley. As the latter is usually on the main shaft, in the majority of cases a ladder is necessary, and in placing the ladder, care should be taken to locate it on the outside of the drive, as shown at A. With the exception of special cases, where the drive shaft is located along a wall, the ladder should never be placed in the position B, and when such is absolutely necessary the shaft should be stopped and the belt run at a very slow starting speed.

When standing on a ladder for this work the body should not be in a strained position, and one hand should be placed on a fixed object for support. For the lighter sizes of belts it is seldom that the speed of the driving shaft is reduced, as the knack is soon acquired of running the belt on. On the heavier belts the work is more difficult, but dexterity is attained with practice. When the belts are very heavy or extra tight, or with a load on the belt, "snapping on" is not so easy, and slipping of the belt is often necessary, while speed is accelerating.

Periodical Overhauling Advisable

To make certain that you are getting

European Conditions As Seen By C. J. Warren

Representative of Remington Typewriter Co. Gives Some Interesting Side Lights on Industrial and Commercial Activities in Europe—British Ships go to Germany for Repairs

THE BRITISH people have been looking forward anxiously, and with high hopes, to the time when their exchange should improve," said C. J. Warren, of the Remington Typewriter Co., when speaking about his recent trip of eight and a half months abroad, which covered central and Western Europe as far north as Helsingfors, as far east as Dvinsk, and as far south as Northern Italy.

"The time has come, and with it disappointment," continued Mr. Warren. "They are essentially an exporting nation. When I went over this last trip the pound sterling was $3.60, to-day it is $4.46. They are finding out that their foreign customers cannot afford to pay such rates for the pound sterling, when francs, lire, marks, etc., can be bought so much more cheaply. This is hurting British business seriously. It has brought into effect various public measures to relieve unemployment.

"During 1919 and 1920 I had found a shortage of coal. That trouble no longer exists, but the prices are so high that, together with the attitude of British labor, British ship owners are being driven to send their vessels to Germany for repairs. This is unprecedented in the history of their shipping.

"Another development, of interest to Americans, is taking place. The domestic servant problem has reached the point where the Britisher, who does not know America, thinks it is simply 'awful.' This together with the high price of coal, is bringing about the introduction of 'central heating plants,' or furnaces as we would call them, to replace their customary grate fires.

"In Holland, the outstanding feature to the traveller is the high prices. Switzerland is the only European country where living is more expensive at the present time. Holland has valuable products to export, principally from her dairies. Her colonies are of great value in her economic life.

Conditions In Germany

"This trip my business took me at different times to Germany or through different parts of it en route to other countries, so that I had opportunity to study it as a whole. I made it my business to note the number of chimneys smoking, and size up in a general way the various industrial districts of that country. While of course different industries varied, it seemed to me that the country as a whole was producing about thirty-five per cent. of capacity. In talking this matter over with a prominent German who is connected with different interests, he called my attention to the fact that Germany had, during the war, doubled her pre-war productive capacity. He stated that if I would deduct half of my chimneys for wartime construction and take the percentage smoking of the remaining half, I would be remarkably close to the official figures, which showed the present German production to be just under seventy per cent. of pre-war production.

"There was more building going on in Germany than in any other country I visited. It was well distributed, both urban and rural. In Berlin I was much interested to see three large banks adding two or three stories to their present edifices. This was said to be necessary to house their increased staffs. Most of the construction, however, was of a residential nature. Occasionally new buildings were seen going up in an industrial plant.

"There was less unemployment in Germany than elsewhere. There was suffering among people with fixed incomes, such as widows, old people, also school teachers and others whose incomes have been increased but relatively little. Few people in this country realize what the drop in exchange means to the people of Europe. Before the war living was much cheaper in Germany than in the United States.

"Then a thousand marks was equal to about $250.00. Now a thousand marks is worth about $3.00 and prices of the necessities of life are much higher. We do not know what economy is in this country. If it were not for the fact that the simplest home grown products, such as potatoes, beans, etc., have not gone up in price in proportion to the drop in exchange, life would be hardly possible for some people. And yet the poor in Germany are better off than the same classes in Poland and Austria.

"Last autumn many retail stores in Berlin had practically empty shelves. Sometimes they would refuse to sell more than one pair of stockings to a person. Many stores frankly asked foreigners from 25 per cent. to 50 per cent. more than their regular prices. This did not seem unreasonable to me. I am convinced that the lack of stocks was due to the Germans themselves. When their exchange was dropping most seriously the people soon realized how much less a thousand marks would buy one week than it would have bought the week before. They decided it was bettter to save or hold most anything except money, and therefore rushed to the stores and bought articles of all kinds. It is true that the large hotels of Berlin were occupied almost exclusively by foreigners to whom most German prices looked very cheap. The total number of such travellers was not enough, however, to account for the depletion of retail stocks.

Exporters After Business

"As far as Europe is concerned, German exporters are pushing their wares more energetically in the countries of low exchange value than elsewhere. While we are feeling the German competition keenly in some markets, my feeling is that in general she is less able to supplant our foreign trade than she was before the serious drop in her exchange. This is particularly true in industries using any imported materials. Labor is generally considered less efficient than formerly. Some of her industries were so specialized that one process was finished near the coal fields. The partly finished goods were then transported to where there was a better water supply, or to where the necessary chemicals were produced.

"Their transportation system is not functioning so as to allow the regular and systematic supply of the partly finished goods to the different plants as is absolutely necessary for economic production. In some cases the new frontiers have come in between the different units necessary for the completion of a given article. This has made necessary the securing of certain passes or customs clearances for the shipment of partly finished goods from one plant to another. Delays occur in spite of all that can be done. This makes economical operation impossible in certain plants and processes.

"There are other difficulties which the manufacturer in Germany has to face; export duties and ever increasing taxes. While wage scales look cheap when reduced to dollars, it must be remembered that in many instances such scales have had to be increased at thirty-day intervals when exchange was dropping. This is one reason why some German manufacturers have refused during recent months to accept any orders, except at market prices at time of shipment."

"In considering Germany's position as a competitor it is necessary to bear in mind that she formerly drew many valuable supplies from her foreign colonies, Alsace-Lorraine, and those ports of Silesia which she no longer controls. If she gets supplies from these sources to-day, she does so in competition with others and not on any preferential basis. The lower her exchange drops, the more difficult it is for her to buy raw materials in the open market and manufacture them into merchandise which it is profitable for her to export.

"While certain kinds of goods can doubtless be manufactured to better advantage to-day in Germany than elsewhere, each line must be considered sep-

arately. Another point which must not be overlooked by any one who is considering manufacturing in Germany is that should the German exchange become stabilized or improve, prices of commodities will drop much more rapidly than will wages. Germany will then encounter the same difficulties which Great Britain has recently with the improvements in her exchange.

Situation in Denmark

"Denmark's currency has been depreciated more than that of Sweden, but less than Norway's. It is essentially an agricultural country. Its farms furnish its chief exports as well as a large share of its food. The free port at Copenhagen is important in foreign trade. While business has been dull there, it has not suffered as seriously as the other Scandinavian countries.

"Norway: Its principal industries are shipping and fishing. They have been suffering extremely during the world-wide depression. Two of the largest customers of their fishing industry were Spain and Portugal. When Norway adopted a form of prohibition which largely stopped the importation of Spanish and Portuguese wines, those countries retaliated by obtaining their supplies of fish elsewhere. The situation is still serious in Norway.

"Sweden: Sweden is an important producer of high grade iron and steel, and certain steel products, wood pulp and paper. It is a much more industrial nation than any of the other Scandinavian countries. Its agriculture, shipping and fishing are considerable. Although this country has been very pro-German throughout the war, I found much less German competition here than in countries with a more seriously depreciated currency. Stockholm is one of the European capitals where the Bolsheviks have maintained an important mission. Business is still far from normal.

"Finland: Finland's principal industries are fishing, wood pulp and its products. While the Finnish mark is not depreciated to the extent of the German mark, I could not find any cause for its being as low as it is, especially when compared with the currency of the other Scandinavian countries.

"There is little intercourse between Finland and Russia. There is no love lost between them. The Bolsheviks have crossed the border several times and then been driven back by armed force.

"The Finns are an intelligent, enterprising, industrious race. Their capital is a modern up-to-date, well kept city. Their art and architecture has a character all its own. The poem from which Longfellow took the meter, and upon which he based his Hiawatha, is Finnish.

"Esthonia: The old walled Russian city of Reval, the capital, is quite a contrast to the City of Helsingfors, we had left across the narrow gulf of Finland. The Esthonians are proud of their independence. There is regular communication with Petrograd by both rail and water. Business in this country is very limited at the present time, but there is a constant bartering trade with Russia. There is a daily sleeping car service to Riga, Latvia.

"Latvia: Riga, the capital, might be described as a typical Western European city. It has many broad streets, parks, etc. The hotel service was very good, but the buildings and equipment showed the wear and tear of six years of war, under opposite sides at different time. With their depreciated currency they could not be expected to refurnish the hotel at the present time. Until the ice closed the Baltic sea a few people there with Bolshevik trading licenses had been sending small sailing vessels into Petrograd with miscellaneous cargoes. They returned with equally miscellaneous cargoes, but the business was profitable. There is also rail communication with Russia, but direct line to Moscow, the line to Petrograd is not in operation. As trade with Russia increases and until such time as it is practicable to maintain direct relations with the leading Russian cities, Riga will, I believe, be the leading base of operations. There are through sleepers daily to Paris, and to Ostend for London.

Conditions Bad

"From here we turned east to Dvinsk on the Latvian-Bolshevik frontier. The vicinity of this city looks like a section of the western front with no sign whatever of any reconstruction. The people seem too poor and destitute to do anything. We travelled with one man who seemed as warm as we did. His coat was lined with sheep skin with the wool on and the outside was neatly patched, but some of the patches were of burlap. The place was buried in ice and snow, but children ran by us in rags and tatters through which we could actually see their skin.

"Plain food was available in the so-called hotels and restaurants to those who had the price. When we figured the prices into dollars, they seemed cheap, but to the poor man who earned rubles, they were awful. The bridges across the Dvina had all been destroyed. A temporary one had been constructed, but most of the traffic was on the ice. We secured an old army truck to take us to the Lithuanian frontier at Kalkuny.

"Lithuania: This country can barely be said to have a sea coast. It has no prominent port. In certain relations with foreign countries it acts together with the other two Baltic States. In other respects it is very closely allied with the people of Northeastern Poland. While very little business can be done there at the present time, we have found it advisable to have it handled by the Polish dealers from Warsaw.

"There are nothing but third-class carriages left on the railway across the eastern end of Lithuania. The service does not connect with that of the Polish railways.

"Poland: Turmont, on the border, is composed of an old freight car for the ticket agent, and two rough buildings of about the same size; one is the custom house and the other a buffet and waiting room. Most travelers have to stand for lack of room. There is one farm house in sight. A through train runs to Warsaw, via Wilna, daily Twice a week it carries a sleeping car. After waiting more than four hours in the cold and dark the Polish train pulled in.

"It was very pleasant to step into the clean, comfortable French sleeping car which was to take us to Warsaw. Conditions there warrant all the philanthropic work which America has been doing. Our first impressions were quite contrary. The furs, silks, and jewels displayed in the large hotels did not indicate need for any such assistance. It developed upon investigation that very little display was being made, or money spent in the large hotels except by foreigners but such foreigners include the Bolsheviki.

"In considering Poland, it should be borne in mind that this country is made up of three sections. Until recently each of these sections was under the domination of a different monarchy, and in each case was exploited for the benefit of another race. The great masses of the population were not educated to become citizens of a republic. But the better class of Poles must not be judged by these masses. They will compare with any race, or people. They have no easy road to hoe, but I have faith in the ultimate solution of the Polish problem. The situation resulting from depreciated exchange is similar to that in Germany, but worse. There are sleepers daily to each, Paris, and Ostend for London via Berlin.

Picture of Russia

"The picture I shall try to give you of this country is a composite one. It came from several men living at present in different countries just outside of Bolsheviki Russia, but each one of whom knew Russia before the war, has been in Russia more than once, and has recently come out of Russia. They are all business men, but not men who went into Russia in any such capacity that a stage was set for them as has been too often the case.

"Food and clothing can be bought in both Moscow and Petrograd, from privately owned retail stores. The wholesale trade is really under Soviet supervision, but trading licenses have been issued. Property rights up to small amounts, particularly for the peasants, have been recognized.

"The great mass of the population is destitute, broken in spirit, pitiable. They have nothing with which to buy, and until recently have not been encouraged to produce anything. The large institutions, the big accumulations of capital are gone. Those who hurried

to hide their property are mostly dead and their property gone.

"There was an old custom or habit of the Russians which is now often overlooked. The small and medium sized business men, often the leading men of the smaller communities, the backbone of the country, did not bank their money very often, they buried it. When the revolution came they did not have to hurry to hide all of their property. Out of a pre-war population of over 160,000 people, it is estimated that there may be four or five millions such people to-day. The total business such people could possibly do would be small as compared with the pre-war totals of Russian business. It is believed, however, that as soon as they feel assured on two points that considerable trading will begin. These points are: first, that when they produce the money it will not be taken from them; second, that when they have used the money in the purchase of goods that such goods will not be taken from them.

"One man living outside of Russia who has a Bolshevik trading license has been sending small trading vessels into Russia with miscellaneous cargoes, up to the time the ports were closed by ice this last season. His license read 'to trade in necessary articles.' I asked how he knew what he could send in. He replied that he did not know; that anything could be stopped, but nothing ever had been.

"This same man heard of a town where the— Soviet, if you like—but nevertheless leading men of the town, looking after their own interests wanted to import some goods. He went in person with his wife. They drew up a list of goods they wanted, mostly agricultural machinery and seed, amounting to over $300,000.00. He asked how they wished to pay for it. The reply was 'Is gold good enough?'

"With regard to the present government: it is believed that the men at the head of it are among the cleverest that ever lived anywhere, at any time. It is believed that they themselves recognize that Bolshevism or Communism is a failure and that to undertake to continue it is sure death. To frankly admit it, and right about face, would mean assassination at the hands of their own understudies and dupes. They are considered to have undertaken to swing around gradually to a capitalistic government. They are rather expected to succeed. On the other hand I was cautioned that a man who was investigating the situation as to the possibility of opening commercial relations with Russia, should know that there was a remote possibility of the worst pogrom the world has ever seen, beside which the worst Turkish massacre would seem a child's play.

"Before the war for a foreigner to take part in the diplomatic or social life of Russia the French language was necessary. On the other hand, the foreign language most useful in the ordinary commercial life of the country was German. The Germans forced this situation. The English to-day recognize this situation to the extent that they have gone so far as to organize a company in Berlin, but directed from London, with a view to taking advantage of the German entree to open business in Russia. Germany and England (the latter not too close a second) are the two European countries able to handle and already working to secure Russian trade.

"Czecho-Slovakia: Prague is an interesting city, but not a cosmopolitan capital. It is a tremendous job to organize a national government and get it running, where there has not been any. They are doing remarkably well, although there still remain serious problems to be solved. Their industries are generally more diversified and better developed than those of most of the other new European countries.

"The Germans are working this country to the utmost, but are not met with an over warm reception by the elements who have feared a possible absorption by Germany.

"Austria: As in western Europe, all roads lead to Paris, so in central and southwestern Europe all roads lead to Vienna. Some of these roads were first built by the Romans. Vienna was strategically located. No artificial political boundaries are going to change it. Vienna is going to continue to be the most important city in the commercial life of that country. Their new political neighbor on the north is an important producer of beet sugar. She undertook to rule that her sugar crop should be sold direct from Prague and not through the former channels in Vienna. Finally the unsold stocks became so large as to cripple the industry. The Government regulations were withdrawn and within two weeks after the sugar was offered on the Vienna market, the stocks were disposed of for distribution over a wide territory.

"There were over 20,000 men in the University of Vienna; of these there were 700 listed by a welfare organization who were living on from three to four meals a week, and had no rooms to sleep in. They gave a small tip to the porters of the cheap cafes which were closed at 1 p.m. and slept on the benches without bedding. Some will not live through such an experience, but our American youth must look to its laurels if it is going to be a match for the men who have gained their education at such a price.

"The political and economic situation seems in some respects to be an impossible one. Utter ruin has repeatedly been promised since the armistice. Industrious, intelligent men, with families to support, die hard. Our company is selling a very limited amount of goods there and is getting paid for them.

"Italy: Italy is in far better condition as regards labor than she was a year ago. At that time the threat of revolution was rife. Not a manufacturer or proprietor there knew 'where he was at.' They have had some hard times, but there is now no danger of revolution. Several laws have been passed for the protection of labor. Employers hesitate to take on more work than they can do with their regular number of employees, because of the legal difficulties in discharging men. Compensation for several months or even a year is allowed frequently. There is a marked tendency in this direction all over Europe which should be watched by all Americans employing men in Europe. Italy seemed to me second (Germany first) in the amount of building there was going on.

Conditions In France

"We hear much criticism of France for not demobilizing more. If the environs of New York City had been devastated as has the country near Paris, and if our arch enemy was at the unprotected Canadian border, and we had no more assurance of what our allies would do in case of another attack than has France, I doubt if we would be willing to demobilize more.

"The excitability of the Frenchman—his socialistic tendencies—are often referred to. Against this the Frenchman has a very strong safeguard which is lacking in his conservative neighbor across the channel. The average poilu, if not a property holder, is the son of a property holder. Extremists may write and talk and be quelled, but I did not find the underlying resentment towards the landlord that existed where there was the constant fear that if the next month's rent was not paid the wife and kiddies would be put on the street.

"The owner of a large property in the center of Paris could not legally raise his rents. When French exchange was lowest and coal was at its highest price, the landlord came frankly to his tenants and stated that their leases included heat. He showed them that his total income from rent would not pay his taxes and coal bill alone without allowing anything for porter and cleaning expenses regardless of upkeep and income. He stated that unless they could come to an amicable arrangement whereby the tenants would make an extra payment for coal he would be compelled to burn in the furnace only the materials gathered in the scrap baskets. The tenants recognized the justice of his position and agreed to an additional payment for coal.

"Due largely to the loss of man power and the men under arms the unemployment situation has been less serious in France than in several other countries. There is a shortage of skilled labor. In a few lines of business at least conditions are quite as encouraging in France as anywhere in Europe.

"Switzerland: This little country has no foreign colonies. Their exchange has been the first to return to the pre-war normal. Her lace, watch and dairying industries have been crippled as never before because their foreign cus-

Mechanical Control of Oxy-Acetylene Torch

Cutting Metal by This Process Approaches Very Closely the Maximum Theoretical Efficiency—Obtaining Any Desired Shape By Means of Templates—Application of the Radiograph

By FRED J. MAEURER

IN bringing before you these photographs of very unusual machine cutting operations by the various types of machines, we particularly call your attention to four essentials of cutting that can be obtained only by taking away the human element and substituting electric power for motion and mechanical means for holding the torch; these four things are—low oxygen consumption, speed of cutting, accuracy and smoothness of cut.

Of the four, the consumption of oxygen is by far the most important, as engineers and plant managers are always on the watch for information that will enable their operators to cut down oxygen consumption without cutting down production. It has been proven time and time again that it can be easily done if the heads of departments would compel their operators to follow the instructions sent out by the manufacturers of equipment with each torch. Each size tip is so drilled that it operates at its highest heat efficiency if the pressures are used as prescribed. For each thickness of metal to be cut they tell you what size tip and pressure to use and also to tell you at what speed the torch should travel. This isn't guess work on their part; they know from thousands of experiments they are always carrying on that it is right, and if they can put a certain thickness with a certain tip and pressure and move the torch at a certain speed, it surely follows that you can do likewise. Our company maintains a large force of expert service operators traveling all over the country, and in all kinds of plants both large and small instructing the users of equipment to follow the instructions as to tip sizes and pressures thereby saving vast amounts of oxygen, also giving instructions as to the more modern methods. That goes for all makes and styles or oxy-acetylene welding and cutting torches on the market.

It does not take long for a hand cutting operator to get in a rut. Instead of trying to do his cutting with the least amount of oxygen, he will put into his torch a tip three or four sizes too large for the thickness to be cut, and use an oxygen pressure absolutely out of proportion to what he should use, just because it cuts easier. In a great many instances, to forcibly impress it upon his mind, we have taken his torch and actually cut metal 4 and 5 times the thickness as the metal he was cutting, using the same size tip and gas pressure as he did. It is the writer's opinion that this is the chief cause of oxygen waste and can be worked out and stopped with the proper co-operation.

Metallurgists, chemists and research men tell us that it requires a given amount of oxygen to consume or oxidize a given amount of weight of steel, and if a greater amount of oxygen is used without adding additional weight to the steel, a waste of oxygen is the result. The writer has a long laboratory report from a well-known metallurgist who claims that the most economical proportions are one cubic foot of oxygen to twenty-two hundredth pounds (.221 lbs.) of steel.

In trying to check this up, we have made some very interesting tests, covering quite a period of time with both hand cutting and machine cutting, selecting half inch steel plate to experiment on, using various size tips and pressures, and also various speeds.

Our hand cutting test was cutting over 5,000 linear feet of ½ inch plate, covering 17 days cutting at 8 hours per day, or 136 hours. This time covers moving from one side to the other, but does not include changing of cylinders, as a 10 cylinder manifold was used, cylinders being changed before starting in the mornings. Three different size tips were used at varying pressures, but the best results were had with the smaller tip. The best day's cutting was used, which was 393 linear feet cut, 565 cubic feet of oxygen consumed. This means his best average linear feet cut per hour was 49 feet. The speed of cutting averaged 8.16 inches per minute, and oxygen consumption 1.43 cubic feet per linear foot. This is truly very remarkable hand cutting which every operator well knows.

To give you an idea as to what the human element actually means in hand operation we find that on one of these seventeen days having the same identical working conditions and the same thickness of plate to be cut, weather conditions also good, he cut as low as 258 linear feet, another day 298, another day 347, and another 360. This test conclusively proves that a hand operator cannot keep up a constant speed several days at a time.

In carrying on our machine cutting tests, we used the same size tip and

This material was prepared by the author, engineer of Airco-Davis-Bournonville Co., for the American Welding Society.

Fig. 3.—Top: Cutting 14 in. square billets with radiagraph.

Fig. 8.—Lower: Edges show smoothness of cut.

Fig. 2.—Top: Machine at work cutting rings from plates.

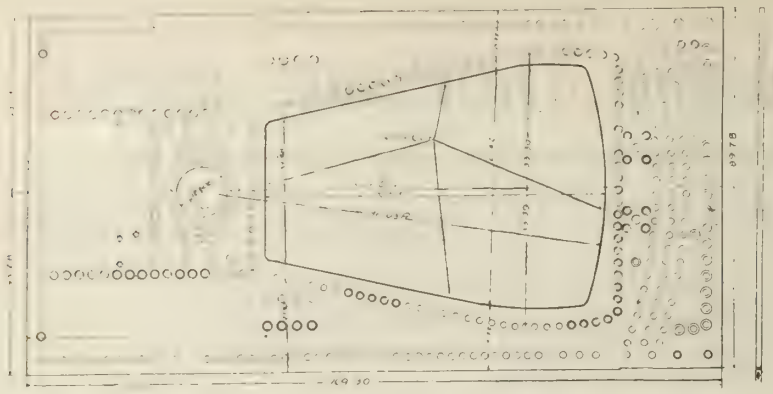

Fig. 4.—Sketch showing accuracy required in cutting plate for gun carriage.

lower oxygen pressures than the hand operator did, using half inch plate, each plate 12 feet long, and obtained a speed of 18 inch per minute and oxygen consumption 1½ cubic feet to each 18 inch of cutting. The width of cut was ⅛ inch, and as one square foot of ½ inch plate weighs 20 pounds and dividing this into 20 pounds we find that we have oxidized .21 pounds of steel with each cubic foot of oxygen consumed, which is mighty close to the figures submitted by the metallurgist. All of the machine cuts were smooth and straight. 2,500 linear feet were cut by machine.

Further checking up on this report, a large steel car plant is at the present time cutting forged steel yokes, 19 linear feet of cutting on each yoke, thickness a trifle over one inch, using the next large size tip at a speed of 12 inches per minute and oxygen consumption 2 cubic feet for each linear foot cut. Our experiments covered over a week's time using three different size tips and various pressures before we found that the tip and pressures used at the present time of these yokes were the most economical. You will note from this that we again come very close to the proportions as outlined by this same report. These cases are only a few of the many that were carried on and we believe they conclusively prove that the most economical steel cutting is done by automatic cutting machines, cutting the waste down to a minimum. These tests do not mean that the speeds mentioned above are the highest that these thicknesses of metal can be cut with machines, as the writer has successfully cut ¾-inch steel at the rate of speed of 28 inches per minute and ½-inch plate at 33 inches per minute.

With further reference to checking up the proportions of oxygen to steel to be used in cutting, we also cut a 14-inch billet, that is, the piece of steel of 14 inches square and the width of kerf was ⅜ of an inch. The oxygen consumption was 100 cubic feet. The amount of steel oxidized would naturally be ⅜ of an inch wide, 14 inches long, 14 inches deep which weighs 20.4 pounds. This shows that for each cubic foot of oxygen consumed on this cut we oxidized .20 pounds of steel.

The writer does not wish the impression created that these proportions are absolutely correct from the hand cutting or the machine cutting standpoint but realizes that it is a wonderful basis upon which we can all operate and if any operator, hand or machine, can better these figures, we can only say, "more power to him." Although we cannot vouch for the correctness of this report we do know from practical experience that we come mighty close to the figures outlined by it.

That there is a vast waste of oxygen in the larger and smaller plants there is no question and engineers are at the present time co-operating with the service men to the limit to cut it down, but due to the fact that a certain amount of their work is done in an emergency, it has been hard work to bring it to their attention, unless some unusual cutting is done in their presence, to make them fully realize that the waste is going on.

I have in mind one case where a competitive test was held at one of the larger steel plants between three different makes of torches in which the writer took part, cutting 12-inch square billets, each operator to make nine cuts. When the demonstration was completed it was found that the difference in oxygen consumption between the three torches was about 15 per cent. The lowest oxygen consumption on one 12-inch cut was 68 cu. ft. Their own operator then cut several billets with about the same oxygen consumption. The engineer in charge of the test asked his operator what size tip he always used and how much oxygen he consumed on cuts he had made before, and he frankly told that he had used a tip three sizes larger than the tip we had used and could only get one cut out of a 200 cu. ft. cylinder. From that day there is very little oxygen waste in that plant as the operators are being checked up continually. This is not an unusual case but it can plainly be seen that something out of the ordinary had to happen before this particular waste was stopped. This operator informed us that he had used a No. 10 tip with 185 lbs. oxygen pressure, and those of you who have had any experience with heavy cutting fully realize that this large pressure travelling through a narrow kerf was cooling the walls of kerf and molten oxide before it had a chance to get half way to the bottom of the billet. The test cutting was done with a No. 7 tip and 125 lbs. oxygen pressure.

It isn't a very easy job to get the officials of a large plant interested in oxygen saving, particularly those that have a great amount of emergency work, but once they do become interested there is no limit to what they will do to co-operate with you to the best of their ability, this is evidenced by the following facts of a very recent case.

(To be Continued)

In the issue of June 15 appeared an item on a Large Bucket Dredge built by Can. Vickers. The h.p. of this vessel should have been given as 1,800 and not 1,400.

Practical Ideas From Practical Men

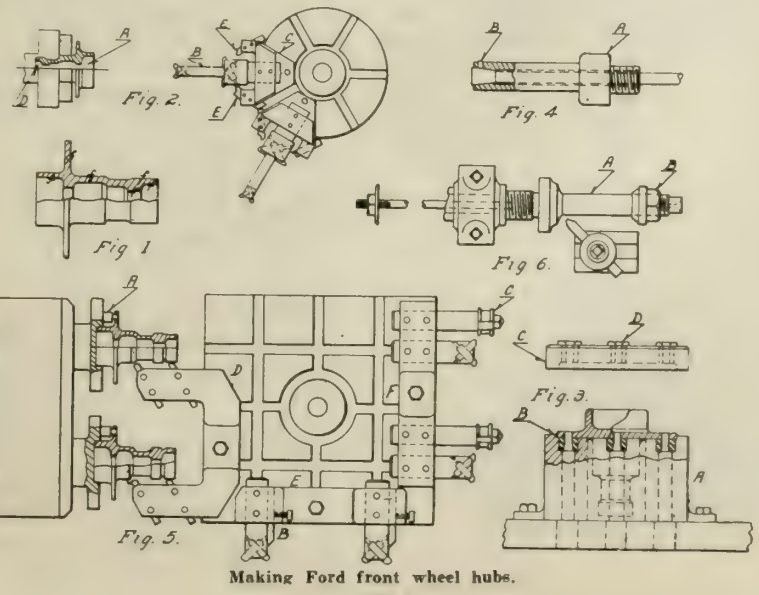
MAKING FORD FRONT WHEEL HUBS

By Geo. Barrett

The sketch Fig. 1 shows the hub which is of malleable iron, and machined at points marked f, and are finished to very close limits by handy operations in Hartness flat turret lathe.

The first operation is boring the seat of outer ball cup and finish for inner ball cup A, Fig. 2. This tooling consists of indexing the turret in two positions, using Kelly adjustable boring bar B, Fig. 2, and a special fixture C, having a roughing and finishing tool as shown in the layout.

The stop on carriage of turret is set to give a standard length of hub, from front to inner ball cup seat, so as to allow enough stock to finish outer end. The small end of boring tool B is to finish the bore marked D, Fig. 2; this bore is made true with the alignment of inner ball cup seat A for accurate setting on arbor for succeeding operations. The tools E and F are to chamfer the outside and inside of ball cup seat, and also face to length. All the tools are made from stellite and compound used for lubricant. The machine runs at a high cutting speed, the average production on this operation being 60 per hour.



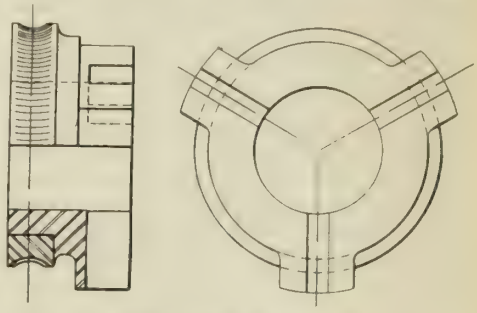
The next operation is drilling for bolt holes which are 13/32 in., and all holes are drilled at one setting, using jig as shown at Fig. 3. This is of simple construction, having a base A, Fig. 3 which is bored out at B half the depth of hub flange thickness for centering purposes. The drill guide C, Fig. 3 is placed on opposite side of flange in any position and drill spindle brought down so that drills in multiple spindle will enter guide bushings D, the output averaging 90 per hour.

The hubs are now ready for the outside finishing and consist of the following operations: turn barrel, face flange, bore outer ball cup seat and finish diameter for hub cap thread. This operation is done on a double spindle Jones and Lawson, the hubs being held on a special expanding mandril Fig. 4, which is of the ordinary type operated by air chuck. The inner ball cup seat is now finished with the limits close enough to allow the mandrel to be made a neat fit at A, Fig. 4, and gripped at D by expanding dogs B. The tooling arrangement is shown at Fig. 5. The hub is placed on mandrel and driven by pin A. At first indexing of turret the barrel is rough turned and inside of hub flange faced.

At the second position the bore of outer ball cup is roughed out and chamfered. The turret is next indexed to finish bore ball cup seat, and form outside of barrel for hub caps, using Kelly boring bars and circular forming tools C, Fig. 5. The turret is fed into the required depth and returned, after which the head of the machine is brought in contact with forming tool, using the graduations on cross feed wheel to insure the size for diameter of thread.

The fixtures D, E and F are made of cast iron and having machine head set to zero before boring for tool holders, assures alignment on indexing of turret. This operation averages 30 per hour. The hubs are now ready for the ball cups to be pressed in, which is done on a small hydraulic press. The ball bearing is then applied and retainer rings, also the dust felt. After assembling complete ball cup, they are passed on to an ordinary engine lathe where a light cut is taken off the barrel and hub flange, using a special arbor, Fig. 6.

The final operations consist of threading for hub cap, which is done on an ordinary bolt cutter using a Landis die head, the threading being performed last, so as to prevent damage while work is in transit through the different operations.

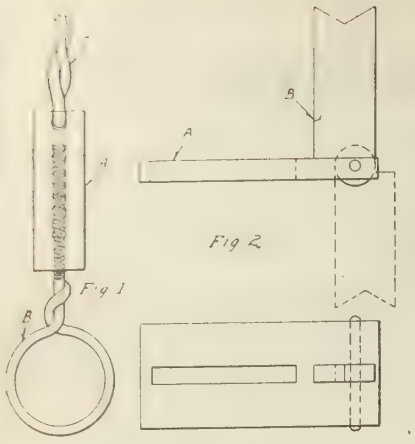


Making Ford front wheel hubs.

REPAIRS TO CUTTING OFF MACHINE

By N. F. P.

On a certain cutting off machine the retaining member that holds the jaws is made integral with the worm gear that operates it; the jaws bearing on three cams and being revolved, close upon the work. In the case of material being cut off in the machine of the same size, it soon becomes necessary to discard the steel casting and order another. If the worm gear be turned away on one casting and a worm gear cut from another, it could be shrunk upon the casting in a different position and dowelled in place.



Cutting-off Machine Repairs.

SUPPORTS FOR VICE WORK

By H. M.

When doing work of any description on bars held in the vice the necessity for some kind of support arises when the work is long. This is quite apart from the actual weight as even light bars of drill rod will sag sufficiently to make it difficult to hold and adjust in the vice at the same time. The common shop support stand, made of a floor plate and several pieces of iron pipe and fittings to make it telescopic is generally used and is no doubt an excellent support to use around a shop, but when a workman desires, for instance, to saw off a short length of steel he feels disinclined to go hunting around the shop for the stand. Other instances of a similar character arise that make the adoption of some kind of permanent support a profitable undertaking providing the kind used is simple to make and operate.

Work-holding devices.

Two such supports are here illustrated. The one shown in Fig. 1 has a wider range owing to the adjustment provided by the threaded wire. The piece A is made of 1¼ in. cold rolled, drilled and tapped for the thread on the end of the loop B. The wire C, which is connected to the ceiling supports the fixture. When not in use the loop may be placed over a nail or hook on the adjoining wall.

The support shown in Fig. 2 is made of rough strap iron, the piece A being slotted as shown for adjusting to position on a bench. The swinging piece B is pivoted in an end slot and has a heel for resting on piece A when in a working position. The dotted portion shows location of support when not in use. Piece A can be made to slide beneath bench if desired.

HOW TO FIGURE THE COST OF TIGHT BELTS

By W. F. Schaphorst

In power transmission through belting we have some rather peculiar conditions to contend with. Run the belts tight and the bearings will consume too much power. Slacken the belt and it may slip and we then have the power loss due to belt slip which amounts to one per cent. of the power for each per cent. of slip. With a given belt, then, it may be possible to permit slip to some extent and still save power by running the belt rather loose. But, again, by permitting slip, we are permitting our belts to wear away faster, and the cost of belt renewal may be considerable. It is evident, then, that the ideal condition is to run belts slack if possible, at the same time preventing slip. This condition is possible and is being successfully accomplished by means of proper belt care.

To emphasize the value of running belts properly I have developed a formula which gives the money saved per year by converting a tight, slipping belt drive into a loose, non-slipping drive. This formula includes the cost due to power absorbed by the journals and the power lost through slip. It does not include the cost of belt wear, though, that is a factor that cannot easily be computed mathematically, if at all. Here is the formula:

Cost per year in dollars=

$$\left(\frac{W V^2 (T-t)}{17{,}688\ T\ t} \times \frac{S\ P}{100}\right) C\ N\ D$$

where

W = Weight in pounds of the engine flywheel;

V = Velocity in feet per second of the periphery of the flywheel while running at normal speed;

S = Per cent. of belt slip saved due to belt care and improved methods. For example, if the belt slipped 4 per cent. while running tight and 2 per cent. while running slack, the saving would be (4 minus 2 equals 2) 2 per cent., which should be used in the formula.

P = Horse power of the engine.

C = Cost of power in dollars per horse power hour.

N = Number of working hours per day.

D = Number of working days per year.

T = Time in seconds required for the engine flywheel to come to a dead stop after shutting off steam or gas. The steam or gas should be shut off as quickly as possible. Engine should be driving the belt and pulleys only and driven machinery should be thrown off of the line if possible, in order not to interfere with the test. T, then, is the time required to come to a stop with belt running slack.

t = Time in seconds required for the flywheel to come to rest with belt running tight.

It is evident that T will be greater than t, because with the lessened power consumption of the bearings it will take longer for the stored energy in the flywheel to be consumed. This formula requires at least four tests: First, the belt slip while running tight; second, the stopping time while running tight; third, the belt slip while running slack, and fourth, the stopping time while running slack. Should it be found that there is more slip when running slack than when running tight, the value $\frac{S\ P}{100}$ would be negative, and it may be found that the advantages of slack running are lost. Whatever happens, this formula will tell the truth.

Let us choose a concrete example, where:

W = 3,000 pounds.

V = a mile a minute, = 88 ft. per sec.;

S = 3 per cent;

P = 200 h. p.;

C = $.015;

N = 12;

D = 300;

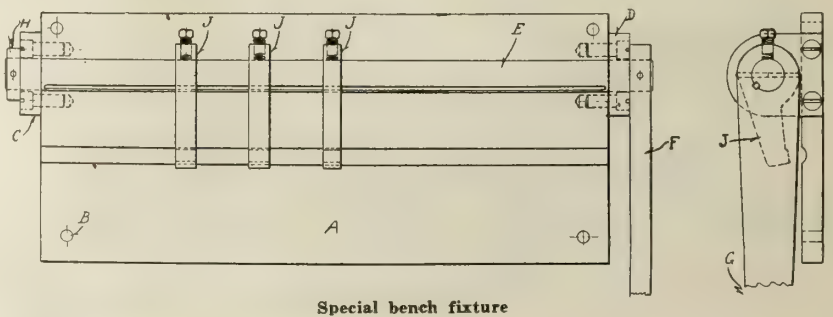
T = 180 seconds;

t = 150 seconds;

$$\left(\frac{3{,}000 \times 88 \times 88\ (180-150)}{17{,}688 \times 180 \times 150} \times \frac{3 \times 200}{100}\right)$$

$.015 x 12 x 300 = $472.

A saving of four hundred and seventy-two dollars per year should make a test like this well worth the while of any power plant engineer.



SPECIAL BENCH FIXTURE

By H. M.

An interesting fixture which was used so that an operator would be free to employ both hands on effective work without being obliged to use one hand for holding same is illustrated herewith. This shows a bench plate A which is held down by bolts through holes B. This has attached thereto a plate at each end C and D through which passes a shaft E. On the outer end of this shaft is a lever F to which is attached a foot treadle (not shown) which is connected at end G. This foot treadle could be any of the simpler types used for general manufacturing purposes its function simply being to rock the shaft radially. A collar H in combination with this lever (both being held on by pins) prevents the shaft from moving endways.

Placed at various distances along this shaft are pieces J keyed in position and adjustable on the shaft lengthwise they being held at any position by screws. Three of these are here shown although it is obvious that more could be employed if the nature of the work necessitates it. These are known as fingers, they being used to grip work placed between them and the bench plate A when the lever is caused to operate by the foot treadle. These fingers may of course be shaped so that they are adaptable to most any class of work. They could go under flanges or inside of casting webs as desired and for some classes of work it would be advisable to omit the keys so that they could be adjusted readily for accommodation to gripping irregular heights, all of which makes this simple tool a very useful one.

Fig 1.

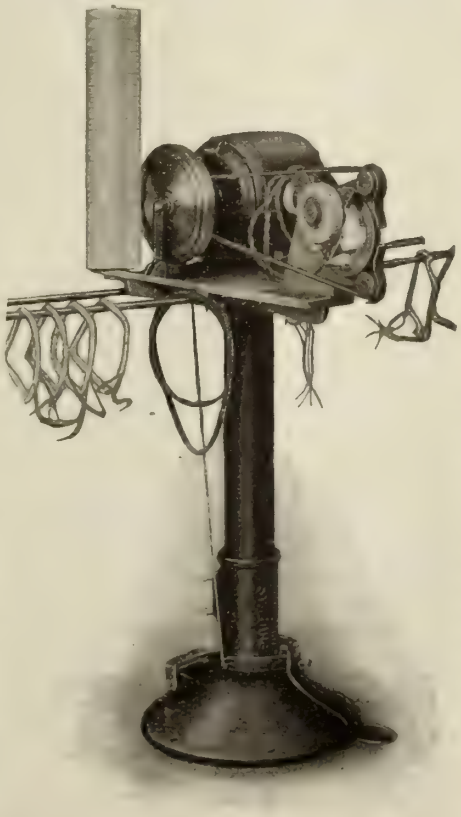
Special bench fixture

New Things in Shop Equipment

PRESSED STEEL HANGER

There has recently been placed on the market a pressed steel hanger suitable for lineshaft work where excessive vibration is not encountered. The bearing floats in the hanger so as to align itself with the shaft. Set screws equipped with locknuts permit bringing the bearing to the proper height and lateral position. The hanger is being manufactured and marketed by the Dodge Sales and Engineering Co. of Mishawaka, Ind.

CYLINDER LAPPING DEVICE



A device for lapping the bores of automotive cylinders has recently been offered to the trade. The apparatus is designed with special shoes which have contact with the cylinder bore and are held by flexible connections at one end of a shaft. Two sets of these shoes are provided and are easily removed when desired. One set bores 2¾ in. in dia. while the other set is adapted to diameters of 3½ up to 4¼ in. These shoes are adjusted to the size of the cylinder by means of a taper attachment. When adjusted to the desired size the shoes can be locked by means of lock nut clamp. A disc is mounted on a shaft to regulate the depth of the cutting tool. The shaft may be driven by an electric or air driven motor or may be attached to the tail stock of a lathe. Cylinders may be locked successfully without removal from the chassis of the automobile. The finished work is accurate both to size and parallelism. This lapping tool is being manufactured by the Stinson Engineering Co., 598 Sixty-Eighth Avenue, Milwaukee, Wis.

ANGLE-PLATE GRINDING ATTACHMENT

The principal feature of a 12-inch, motor driven angle-plate grinding attachment, which has just been placed on the market, is the inclined slide, which allows of movement in one plane for both feed and adjustment of the height of the spindle. The maximum efficiency is thus obtained with the simplicity and rigidity of a single slide. The gross shaft diameter through the motor is 1 7/16 in. while a diameter of one inch is used through the wheel. Grease lubrication is used for the heavy duty ball bearings which are mounted in dust-proof housings. These motors are especially designed and built for grinding service and operate at a normal continuous capacity of 1 1/3 h. p. and will develop a complete capacity of 2¼ h. p. The operating speed is 1,800 r. p. m. The net weight of the attachment is approximately 175 lbs. This device is being offered to the trade by Van Dorn Electric Tool Co., Cleveland, Ohio.

MOTOR-DRIVEN TAPING MACHINE

Motor-driven equipment for tape winding, consisting of an armature or field coil taping machine as selected. It is directly belted to a very slow speed motor on which is mounted a cone clutch, giving instantaneous and very fine adjustments in speed, responding to pressure on a treadle. The continually moving member of the clutch is pinned to the armature shaft, which has enough end play to allow of the clutch being disengaged. It is returned to open position by the magnetism of the motor, thus eliminating a thrust bearing and a spring. A combined self-oiling cone driving pulley, brake pulley, and clutch member rides on an extension of the phosphor bronze motor bearing. It is active only when engaged, thus eliminating troublesome "loose pulley" bearings. An automatic brake operated by the clutch treadle enables quick stopping and inching. A switch is provided, handy to the operator with plug and cord on d. c. and single phase, with switch but no plug and cord on 3 phase. Pins are provided for hanging the coils and for storing ten gross yards of tape. Ample clearance is provided for leads and for various positions of coils. The outfit is self-contained and portable, and when equipped with d. c. or single phase motors, may be operated from any light sockets, making it possible to take the machine to the job. These tools are made by the P. E. Chapman Electrical Works, St. Louis, Mo.

Motor-driven taping machine

32 INCH CRANK SHAPER

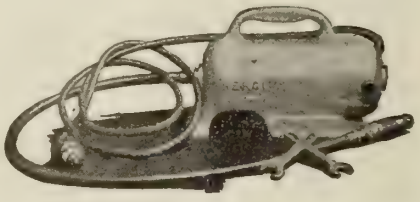
A special 32 in. crank shaper has recently been developed and placed on the market. This machine is especially designed for heavy usage, such as in railway and forge shops. The table has a vertical adjustment of 12¼ in. and a cross traverse of 30 in., the stroke of the ram being 33 in. The table is of the revolving type and a special feature in this connection is the support at the outer end. The machine is provided with a simple gear mechanism all of which is enclosed in a box. The feed cannot operate during the cutting stroke of the ram and it is not necessary to touch any moving part when changing speed. Four changes of speed are provided in a gear box and these are engaged by means of a ball lever on top of the box. The starting and stopping of the machine is under the control of the operator by means of a long lever reaching from the clutch to a point close to the operating position. The brake is automatically engaged when releasing the lever. Machines are constructed for belt drive but may be fitted with motor equipment if desired. Helical gears are used throughout and these are made of steel or semi-steel. All shafts are hardened and operate in bronze-bushed bearings. Tubing is provided for oiling the internal bearings. It is stated that these shapers work very accurately on the longest work within the range of the machine. They are manufactured by the R. A. Kelly Co., of Xenia, Ohio.

SENSITIVE DRILLING MACHINE

A new design of sensitive drilling machine has recently been offered to the trade. These machines are constructed on the unit principle and in two types, bench and pedestal, and can be made in combination of from one to eight spindles. The maximum capacity of the drill is four holes ¼ in. in dia., steel, iron or brass. The three spindle speeds provided are 5,700, 8,000 and 12,000 r.p.m. These speeds however may be altered to suit varying conditions. Dust-proof metal oil retainers are provided on all ball bearings, and the only revolving member exposed is the drill spindle. Vibration and noise is reduced to a minimum by means of helical gear drives. This speed changing arrangement is an outstanding feature, as a single turn of a handle automatically releases belt tension, shifts the belt on the cone pulleys in such a way that the belt is removed

from the large pulley first. When the belt is shifted the tension is automatically adjusted to the new position. An aluminum guard is provided for the protection of the operator. An adjustable step stop is provided for the travel of the spindle. The operator can adjust the position of the feed lever to suit his requirements. A one half h.p. motor is mounted on the machine and a drive may be obtained either through a belt or direct connected. These machines are manufactured by the Fosdick Machine Tool Co., Cincinnati, Ohio.

MEASURING WIRES



For the special purpose of measuring threads, angles and profile a set of wires has recently been placed on the market. These wires are made with great accuracy and are practically perfect as to roundness, uniformity of diameter, and size. The size of these wires is standardized by light waves. The wires are 1⅞ in. in length and are lapped the entire length. The wires provided for screw set measurement are known as "test size wires." The purpose of these wires is to detect any error in the angle of the thread, the error may be easily checked by taking a measurement with the next larger size of wire. The set of wires is placed in glass bottles thus protecting them against loss or breakage. On the outside of the bottle is a label which gives the diameter of the wire, also formula for the measurement of the pitch diameter of the screw thread. These wires are put up in small balls, 20 balls to a case, and are manufactured by the Van Keuren Co., Boston, Mass.

NEW LINE OF TAPS

A line of carbon and high speed steel taps, having a special feature known as the "sharpening face" flute has recently been introduced to the trade. When sharpening this type of tap a round faced grinding wheel is used so that a face is produced that gives a top rate to the teeth and ensures a clean and free cutting tooth. After the taps are hardened they are ground to size and final shape, thus removing all decarbonated material and eliminating errors due to distortion in hardening. It is stated that the teeth are not relieved eccentrically as is usually done in the ordinary taps but are given a special form of relief that is peculiar to this particular type of tap. With the exception of the first four or five teeth, the cutting part is concentric with the outside diameter. A peculiar feature of this tap is that the centre portion for about five teeth is parallel, after which there is a gradual taper towards the shank, so that at the very end of the thread the tap is 000125 in. under size. It is claimed that this design reduces the tendency to bind and provides a free cutting tooth, and due to the concentric shape of the body portion of the tap, these grindings may be carried to a considerable extent without diminishing the diameter of the tap. These taps are being manufactured by John Bath & Co., Worcester, Mass.

MOTOR-DRIVEN FLEXIBLE SHAFT

A motor driven flexible shaft outfit, the motor of which is enclosed in an aluminum casing having a base and handle vertical with it, has recently been placed on the market. A current of air is circulated between the wheel and the armature winding by means of a ventilating fan. The bearings are also cooled by a current of air passing between the scope of the sub-bearing and through a

Motor-driven flexible shaft.

series of holes around the bearings. The flexible portion of the shaft is ¼ in. in diameter, 3 ft. long and wound with wire. The outside covering is of whip cord; 6 ft. of drop cord with an attachment plug are provided with each motor. No external binding post is necessary as the cord is fastened inside the end plate. It is adaptable to all work ordinarily handled by flexible shafts equipment. These tools are being placed on the market by the Hergi Mfg. Co., Bridgeport, Conn.

SELF-OPENING STUD SETTER

A self-opening stud setter known as the Jarvis has recently been placed on the market. The tool is simple in design with all parts hardened, and providing a quick grip and release. These setters are made in three sizes with capacity of the small size up to ½ in. studs, the medium size taking studs up to ⅞ in., and the larger size handling studs up to 1¼ in. diam. Standard shanks are provided with these tools but shanks of special dimensions can be furnished if desired, also special sizes of jaws. These stud setters are being manufactured by the Geometric Tool Co., New Haven, Conn.

CENTRE LOCATING PUNCH

A centre-locating punch which is of great use to toolmakers and die-makers in quickly and accurately locating centres of holes has recently been placed on the market. It is really a combination prick-punch and scriber. One of the methods of using the device is to mount it on the cutter-arbor of a milling machine, with the punch perpendicular and with the part to be laid out attached to the machine table. Then the centres of holes to be bored later may be located by shifting the work beneath the punch by using the adjusting screws, of the table and saddle. By using the dials attached to these screws, centres of holes may be located within the limits of accuracy of the machine. The prick-punch is held in its upper position by means of a coil spring. When it is desired to make a prick mark the top of the punch is tapped with a hammer. When all centres have been located the work is mounted on the face plate of a lathe and bored in the usual manner after centering by means of an indicator. The tool may also be placed in a horizontal position on the cutter arbor and in this position may be used to locate work in a vertical plane. The tool may also be attached to a dividing head and used in the vertical or horizontal positions or at an angle. By pressing the lower end of the punch down against the work a scratch point is placed in contact with the work, and this sharp point may be used for scribing circles as the work is moved past the tool. This application is very useful in laying out dies. The punch is hardened and ground all over and is also lapped where it is contained in the bearing. A collar on the top and one on the bottom of the punch of the same diameter, facilitate the alignment of the device. The holes in the supporting member of the device permit the mounting on either ¾ or ⅞ in. dia. arbors. The tool is manufactured by B. F. Johnson.

Tenders are being taken for the erection of a school house at Onslow Mountain School Section, Colchester County, Jersey City, N. J.

VALUE OF KEEPING TOOLS CLEAN

(Continued from page 19)

operations as case-hardening, plating, blueing, etc. The presence of foreign matter, such as dirt, scale and other substances, will prevent the proper action of the chemicals and frequently result in the rejection of the finished work.

Systematic Cleaning Advisable

Systematic cleaning should be adopted wherever the presence of dirt or foreign matter will interfere with the efficiency of succeeding operations. Where a certain piece of work passes through several operations or departments and the same surfaces are used for locating in jigs and fixtures, it is imperative that these surfaces be thoroughly cleaned to maintain a high degree of accuracy in the details of machining performed at the various points. A cleaning tank or kettle is often used with entire satisfaction for work of this character. When a jig or fixture is taken from the store or tool room it is good practice to have a chemical solution in which to dip it so as to remove any foreign substance that may be adhering to locating surfaces.

Various methods may be adopted for cleaning of product and equipment and the best system must be determined by the individual requirements of each particular case, but whatever the conditions the practice of cleanliness is a profitable one to any firm desirous of minimizing waste and likewise presenting a more accurate product.

The braking of light loads is also of considerable importance when the crane is driven by a direct-current series motor, to prevent it running at an excessive speed.

WARNER AND SWASEY TO BUILD TELESCOPE

A contract has been awarded to the machine tool firm of Warner and Swasey Co., Cleveland, Ohio, for the construction and erection of a large reflecting telescope for the Ohio Wesleyan University at Delaware. This instrument will have a sixty-inch reflector with a tube twenty-five feet long, and will rank among the large telescopes of the world. The telescope will be purchased with money from the fund of $250,000 which has been donated for the equipment and maintenance of Perkins observatory by Prof. M. H. Perkins of Ohio Wesleyan. Prof. Perkins has been in the mathematical department of the university for many years. Announcement of the contract was made by Prof. C. C. Crump, director of the observatory. The machine will be devoted largely to the use of the students and likewise to research.

While the Warner & Swasey Co. has built a large number of notable astronomical telescopes now in use, its main business is the manufacture of machine tools, a function which officials of the company say is sometimes forgotten by scientific men in the more spectacular publicity which attends the building of a big telescope. The design of the instrument will be in charge of E. P. Burrell of the company. The Warner & Swasey Co., is to build the mounting of the telescope and will design the revolving dome in addition. The optical parts will be finished in this country and probably the materials supplied here also. The designing and building of the telescope itself will probably take a year and a half and the work on the mirror and lenses perhaps longer.

The moving parts of the instrument will weigh in excess of thirty tons, the stationary parts about ten tons and the revolving dome and shutter seventy-five tons. Extremely accurate work is required in the building of the moving parts so that the thirty or forty tons of metal can be swung by mechanism so fine that the tiny ray of a star invisible to the eye will fall on the same spot on a photographic plate for three or four hours as the star travels across the heavens.

One advantage of the reflecting type of telescope is that it can be used for photographic work without correction. By means of photography it is possible to reveal the presence of stars which the human eye could never detect even through the largest of telescopes.

The new instrument can be employed in the study of the nature sun spots, of the distant nebulae and, in connection with the spectroscope, of the heat and drift of the stars. With the spectroscope it would also be adapted to the newer method of determining the great stellar distances. The light of each star is collected, photographed and analyzed; the spectroscope measures the brilliancy of the light received. From these two it is possible to estimate the distance of the heavenly body from the earth.

Introducing

NOT so very long ago, we announced in the industrial section of our paper, the arrival of the gentleman pictured below. Mr. Williams has come to Canada as the direct representative of Messrs. Holman Bros., rock drill and mining machinery specialists of Camborne, England, and is prepared to show the advantages of his particular line.

He has been actively engaged in practical metalliferous mining operations over a varied field since graduating in 1904, from what is now the "School of Metalliferous Mining" Cornwall, England.

FRANK WILLIAMS, A. M. I. M. M.

His first appointment was as assistant manager of the West Kitty Tin Mining Co., and in 1916 he was selected as manager of the Grenville United Tin Mines, Camborne. It was in the development of these mines that Mr. Williams first obtained his intimate knowledge of the "Holman" rock drill, which is the specialty of the Holman products.

In 1909 he went to the Federated Malay States as general manager of the Raub gold mines, remaining in that capacity until September 1914, when he returned with several other mining men to England for war service.

Joining his county regiment, the Duke of Cornwall's Light Infantry, he served in France, Belgium, and in Ireland from 1915, onwards, transferring in 1917 with the rank of captain, to the newly formed Tank Corps, where he soon obtained his majority, and was mentioned in despatches by Sir Douglas Haig.

Demobilized from Ireland in 1919, Major Williams undertook the management of Aber Llyn (zinc lead) mining property in North Wales, and relinquished that position in the latter part of last year to take over the representation of Messrs. Holman Brothers in Canada, whose agency is carried by Messrs. Alfred Herbert Ltd., 1 to 3 Jarvis St., Toronto.

To meet Mr. Williams is to enjoy his company, for he is an interesting conversationalist and knows the subject of mining from A to Z.

EUROPEAN CONDITIONS

(Continued from page 26)

tomers found it so much cheaper to buy French or Belgian francs than they did Swiss francs. Even the income from tourists was seriously reduced for the same reason. Switzerland's position is sound but difficult. She followed Belgium in relaxing certain passport requirements.

How Belgium Is Faring

"This little country was the first European country to realize the necessity of getting busy and sawing wood. About six months after the armistice I personally saw in operation in Belgium heavy machinery which had been taken to Germany before the armistice. It had been located, pressure enough had been brought to bear to get it returned and placed on its old foundations. This had been accomplished by private initiative. Much more has been done in the last three years even though an enormous amount of reconstruction still remains to be done.

There is probably less unemployment in Belgium than in any other country in Europe. She was the first to withdraw the annoying war time passport regulations.

REDUCING COSTS BY MEANS OF THE PLANER

(Continued from page 21)

Co., Scotland Locomotive works, Newcastle-on-Tyne, have realized this great adaptability by rigging up a radial planing device actuated by the main stroke disc of the Hiloplane, and placing out the radial segments of boiler saddles in the manner shown in sketch Fig. 3. On this job, the almost incredible saving was achieved of reducing the previous 90 hours, to 19.

It will be seen that a great contributory factor in the foregoing economies is the stirk split field reversing motor drive. This is fitted to all sizes of stirk Veloplanes and Hiloplanes, and is also supplied as a self-contained unit for conversion and existing machines. Fig. 4 shows the unit in question which is furnished with motor generator, reversing motor, and switch-gear, all mounted on one bed plate and wired up complete. The stroke disc being also mounted on the job and driven direct from the reversing motor, no dogs or levers on the planer table are required. Assuming the gear ratio of the machine to be reasonably suitable the only cost of conversion, beyond the actual purchase price of the set, is that incurred in removing pulleys, shortening pulley shaft, setting the equipment in correct alignment, leading in the electric cables to the main switch, and immediately the concrete has set the machine is ready for work.

In other words it is a feasible proposition to run a machine on its old drive up to Saturday noon, and have it running again on Monday morning on its new drive. This is an example of despatch in conversion to my mind unapproached by any other system of reversing motor drive.

143 UNIVERSITY AVENUE
TORONTO, CANADA

Courtesy is Essential

WE HAVE often emphasized on this page the value of courtesy in business. Richard T. Stanley of Toronto is the latest to back us up in our contention, and before the Kiwanians at Toronto the other day he said, "Courtesy costs nothing and it is one of the best business getters we can have."

He later mentioned that he noted a glaring lack of courtesy throughout the business-professional life of America, and at the conclusion of his remarks, the International Kiwanis adopted the idea of "courtesy in business" unanimously. This is a good start, and it is now up to every other society, be it industrial or social, to follow this lead.

The Business Outlook

THE RECENT storm, which spent its fury over certain portions of Western Canada, unfortunately did considerable damage to the crop in some localities. Just how great the loss has not yet been ascertained, but taken as a whole, this unfortunate occurrence should not discourage business men in the East, for good crop reports continue to come in from other parts of the country. The loss incurred will be but a small portion of the total harvest. As far as can be judged at this season, a good harvest appears reasonably sure.

This news is gratifying to the Canadian manufacturer who recognizes that his own prosperity depends upon that of the agricultural community. It will be well, however, to sound a note of warning to those who are too readily inclined to place credence in the view that a good harvest will mean the return of boom times and boom prices.

Whether agricultural prices are likely to decline in the next year or two would be difficult to predict, but in all probability it is safe to say that, unless there is a crop shortage, they are not likely to rise to any great extent. Farmers in the West have, generally speaking, had two or three poor years and the financial gains of a good season would more likely be used in paying off mortgages and other indebtedness than in purchasing the products of the Eastern manufacturers.

Another factor in the situation is the necessity of European markets for a part at least of our agricultural products. Now Europe will be better supplied with farm products than with other things. Although not as yet so well supplied as before the war, her agriculture will be more nearly normal than will be her industrial operations. This means that though she might gladly buy our food products, her industrial position will leave her without means to pay for them, and the tariff wall erected against her by the United States is likely to intensify this position.

The European demand being lacking, or only slight, will tend to depress prices here rather than to raise them; this, in despite of all that the Western farmer seems to expect from that "deus ex machina" the Wheat Board.

The probabilities are then that with good crops the farmer will use the results to pay off his indebtedness to the bank and elsewhere and that any demand that may come for manufactured goods will not be large enough to raise prices above their present level, but will be met by the manufacturer increasing his production if necessary but without increasing the prices of his foods. In other words the prospects are for a period of quiet prosperity, but not for a boom.

Keep Your Appointments

"I LIKE CANADA very much indeed. I have enjoyed my visits to your various lovely cities, but must frankly admit I am horribly disappointed at the way your business men fail to keep their appointments," remarked an English visitor to Canadian Machinery a few days ago.

Upon investigation we found this gentleman had good cause for complaint. He cited case after case, where he had made an appointment for a specified time, arriving there only to find that his party was in some cases too busy to see him, and in other cases had seemingly forgotten the engagemnt entirely and gone elsewhere.

These incidents did not all occur in the same line of business, but embraced about six different fields of activity. Here was a man, with only a certain amount of time on his hands trying to make the most of it. He had planned his interviews carefully, and enacted promises ahead of time. Unfortunately, his plans were rudely shattered, he did not see as many as he wished, and has returned to his country, convinced that Canadians lack that very essential business necessity, "courtesy."

Do we really lack courtesy, or is it the breaking of appointments largely a matter of habit? Luckily, we are not all guilty, but those reading this edition, who have broken engagements, be they important or otherwise, should take stock of themselves for a moment. Would they have liked to be in the other man's place? Certainly not. Well then, if they had no intention of seeing the caller, they should not have made an appointment.

How often we hear the expression: "Oh, I don't want to see that man. I wish I had not promised to see him; tell him I am out." There are other stock excuses but the one quoted is sufficient. The man who forgets a business engagement is not attending to his business, and deserves all the harsh statements one might make regarding such a person. Let Canadian business men take a hint from our English visitor, and once having made an engagement, stick to it. If you do not want to meet some one who is most anxious to see you, have courage to refuse him, but do not lead him on, later failing to keep the appointment, in order to sidestep an awkward situation.

Steel Prices Reflect Firming Conditions

Production Reported to be Upward—Mills Have Situation Well in Hand—Demand for Building Materials—U. S. Railways Heavy Buyers on Car Materials—Jute Twines Up

SMALL TOOLS SHOW INCREASE FOR JUNE

GENERAL firmness in the steel market seems to be due as much to improving conditions in industrial activity generally, as to any fear that the coal strike is going to cause a difficult situation. Reports from Pittsburg and other American points would seem to indicate the period of dulness that marks July and August is going to show a lightness of demand in the open market that is quite seasonal and that buyers are not imbued with all the fear that should seem to exist. Even on the Canadian market one is surprised to find a lessened degree of importance attaching to the struggle now going on.

Among the bright spots in the week's news is the fact that the Canadian agricultural implement industry has made its appearance in the market for pig iron and although tonnages are moderate they show a considerable improvement. Requirements are less for domestic purposes than for export, the feeling in some quarters is that this may presage more permanent business in that direction.

A very strong demand continues for all kinds of material entering into building operations. Metal, lath, structural steel, pipe and in fact all sections show the benefit of this movement and it is not surprising to find a firmness in price trends. Competition among steel mills on this business, however, is developing a marked keenness and there is a tendency here to go after business on lines which, in normal times, are not sought after particularly.

Pig iron markets on the whole show little change. Such movements as that noted in connection with the agricultural implement industry warrant a feeling that the general demand is better. There are good stocks on hand and mills are fully awake to problems that may be created by any aggravated situation emanating from the coal strike and the threatened railway strike. In short they may be said to be in very good position.

Steel and iron bars are holding the advancing tendency noted in last week's issue, with a trend toward the 3.15 mark although the sounder feeling seems to be that such a movement will at best be very gradual, if it does develop headway at all.

Montreal reports activity on part of British mills in galvanized sheets. Large shipments are being rapidly absorbed. There was an advance of 25 cents in 10/16 gauge blue sheets during the week. The automotive industry accounts for ever increasing tonnages on steel sheets and here British costs to the jobbers are steady while reports from United States indicate advances.

In non-ferrous metals there is an unchanged situation. There may be undercurrent of price manipulation but nothing of sufficient importance to work to the surface or to have a direct bearing upon the market.

The machine tool demand continues quiet. Some contracts on technical school equipment have been released. In this business naturally competition has been exceptionally keen and prices not far from rock bottom. Dealers report that May will show marked improvement in the demand for small tools and supplies.

Purchasing agents will be interested in the fact that jute twines for the first time in many moons, are showing an advance from 12½ to 14 cents per pound. It is stated that owing to keen competition, prices in Canada have been somewhat below normal and the change seems to indicate among other things that the market is coming to its senses.

Turpentine, in response to the inevitable law of limited supply and heavy demand, reports an advance of 15 cents gallon.

Toronto

June 28

THAT United States railways are in the market for enormous quantities of material, is a fact that seems to stand out in strong contrast to the Canadian situation. There has been comparatively little buying either by government or privately owned lines here and one explanation may be found in the feeling that the necessity may be postponed until the menace to prices created by the coal strike is over. Moreover, the Canadian railways may feel that the temporary urgency created by a bumper crop can be satisfactorily met. The situation promises some interesting developments and will claim the attention of industry generally. Activity in railway work means much to many concerns, for it goes almost without saying that, when the railways are in the market for large quantities of supplies, there cannot be much wrong with the general situation.

There can be no question that steel prices to-day are firm and that the tendency is upward. Steel bars seem to be an outstanding example. The price is centering about the $3 mark but a very cautious movement towards $3.15 is already indicated. There is no danger of the market at present doing anything irrational for the feeling is that, while business is coming back and the demand improving, it must be welcomed in a sensible way. Following are present quotations, including sheets, which are also in strong demand:

Iron bars	2 90 to 3 00
Steel bars	2 90 to 3 00
Reinforcing bars	2 90 to 3 00
Steel hoops	4 00
Tire steel	3 15
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in base	3 50
Small shapes	3 00
Sheets, black, No. 28	5 00
Sheets, blue ann., No. 10	4 00
Canada plates, dull, 52 sheets	6 00
Canada plates, all bright	6 00
Galvanized Sheets, No. 28	6 00

Pig Iron—No price changes are reported here but demand is developing in quarters that have been more or less dormant. The agricultural implement industry has made its appearance in the market for moderate tonnages apparently to meet an improved export demand. Mill reports indicate good stocks and a problem that is exceedingly well in hand in view of the situation aggravated as it is by the strike outlook.

Non-Ferrous Metals— If anything there is a weakening tendency in this department, but dealers declare that anything might happen. To the average buyer, the undercurrents in the market cannot have much significanre. In a great many instances, the development reaches him only as a slight fluctuation in either direction. The market, meantime, seems to be fairly well supplied. Local quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	6 75
Aluminum	26 00

Scrap Metals.—Some improvement in the foundry situation is developing. Plants at many points are operating on a much better scale than, say, one year ago, and this naturally has had its effect on the demand for scrap. The situation may, therefore, be described as a developing one with no change in prices. Following are local quotations:

Copper, light per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 composition	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	4 85
Light brass	3 50
Medium brass	4 50
Scrap zinc	4 00
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton	9 00
Heavy melting steel	11 00
Axles (wrought iron)	16 00
Rails (scrap)	11 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axles	15 00

Mach. shop turnings	6 00
Sheet plate	14 00
Cast borings	5 00

Machine Tools.—The market continues quiet with now and then a bright spot. June it appears, will shape up as a good month in small tools and supplies. At least that is the report in some quarters. Demand for radio equipment is responsible for some improvement in the demand for certain attachments. In fact this is a field that is not without definite promise in this department.

By some dealers and manufacturers it is felt that the months of September or October should show much better feeling in the machinery demand.

Jute Twines are showing an advance from 12 1/2 to 14 cents. Prices in this department are reported as having been quite below normal owing to what is called "misdirected competition." The firming process is described as more or less a return to reason.

Montreal

June 28

IRON and steel industry activity in the local markets shows no important changes for the last week. Quotations continue to be firm, and in the case of blue annealed sheets, an advance of twenty-five cents is quoted. The base price of steel remains at $2.90, and there does not appear, at the moment, that there is likely to be any change. The new rates on ore and basic steel commodities have not had any direct influence on the local market. Pig iron is not showing much activity and machine tools are quiet. Supplies are moving about the same as usual. The non-ferrous metals are somewhat weaker after their firmness of the past two weeks. The volume of sales is being maintained about as usual. The scrap metal markets are quiet.

Iron and steel—Galvanized sheets continue to be the most active of all the steel products. Large shipments continue to arrive from the British mills but the demand is so great that they are immediately absorbed, a large proportion of them never reaching the warehouse. Tin plates are also arriving in large quantities and are being disposed of nearly as quickly. Prices remain firm in spite of these heavy shipments, as stocks in the warehouses are low, and it appears to be impossible to increase them. Black and blue annealed sheets are also moving well, blue annealed sheets 10/16 gauge advanced twenty-five cents during the week, the improved demand and delayed delivery being responsible for the revision. In this connection, the factors that have been to a large extent responsible for the stiffness in quotations, are that the deliveries of coal and raw materials to the mills have been somewhat uncertain, all of which has tended to hamper production.

The automotive industry is demanding large tonnages of steel sheets, and this demand is increasing from year to year. The delayed deliveries from the point of view of demand, have been caused principally by this factor. British costs to the jobber on steel sheets remain steady while the United States costs are mounting slightly. For that reason jobbers and consumers are directing their attention to the British sources of supply. Only a nominal relief through this channel can be obtained at the moment, as those British mills operating on sheets are well booked with orders, principally from the Orient. It is understood that this market gives a little better return than that of the Canadian field, and as the quantities required in the East are from eight to ten times those required for local consumption, it is thought that there will be experienced great difficulty in diverting much tonnage on short notice.

One jobber has sample sheets on the way out from England, which sheets he expects to use as samples to secure orders from the automotive industry. The sheets are especially rolled for this purpose and it is hoped that a certain share of the auto body and mud-guard business can be secured.

Plates are very quiet. Structural steel and merchant bars are enjoying a littlel better demand. Small steel products are moving well. No general advance in prices has been made. Building operations are still to the fore and contribute in no small way to the demand for sheets, heavy hardware, and small steel products. On the whole, the week has been one of the best for some time past. Local quotations are as follows:

Iron bars	2 90
Steel bars	2 90
Reinforcing bars	2 90
Steel hoops	4 00
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—There is no great change in the pig iron market. Quotations on No. 1 iron still remain at $31.80. The demand is not showing any appreciable improvement, the consumption being rated at nominally ten per cent. of normal. The inquiries and orders come principally from the smaller shops doing jobbing and contract work. The larger foundries are doing little or nothing. The railways themselves are only absorbing a small tonnage. The present demand is far from satisfactory, and in addition to that, there exists very keen competition, as British pig is being offered at a figure slightly below that of local producers. Should the same condition prevail when the demand reaches larger proportions interesting developments would occur, and undoubtedly a buyers' market would be created.

Machine Tools. — Quiet conditions prevail in the machine tool market. During the week no important sales have been made. Inquiries and sales are only for smaller tools and for one only. All orders are very keenly sought. Aggressive sales campaigns are being maintained but the volume of sales does not materially increase.

Shop Supplies.— The demand for small tools and shop supplies is being maintained about as usual. The small contract and jobbing shops are coming into the market fairly freely and there is some demand from the railways and larger corporations. No important price changes have been made during the week.

Non-Ferrous Metals. — A general weakness is shown in this market. Foreign markets are weak and it is their influence that is reflected in the local markets. The volume of business is not falling off, but there is no great improvement. No actual change in quotations has been made. Local quotations are as follows:

Lake Copper	17 50
Electric Copper	17 25
Castings, Copper	17 00
Tin	35 00
Lead	6 75
Spelter	7 75
Antimony	6 50
Aluminum	23 00

Scrap Metal Markets.—Very little activity is shown locally in the scrap metal market. There is some demand for the non-ferrous metal scraps from United States markets, and some small shipments are being made. There is but little demand for the ferrous scraps locally. Some of this scrap is finding its way to Ontario consumers but this business is small. Some figures have been reduced this week but the reduction has no direct bearing on business moving. The holdings locally are small as the dealers do not consider the demand at present warrants them in carrying heavy stocks. The local quotations are as follows:

Copper, light, per 100 lbs.	8 50
Copper, crucible	11 00
Copper, heavy	11 00
Copper Wire	11 00
No. 1 compositon	9 00
New brass cuttings	6 00
Red brass turnings	6 50
Yellow brass turnings	5 00
Light brass	4 00
Medium brass	5 50
Scrap zinc	3 50
Heavy lead	4 50
Tea lead	3 00
Aluminum	11 00
Boiler plate, per gross ton.	9 00
Heavy melting steel	10 00
Axles (wrought iron)	20 00
Rails (scrap)	11 00
Malleable	10 00
No. 1 machine cast iron	20 00
Pipe, wrought	7 00

Car wheel	17 00
Steel axles	15 50
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	4 00

Pittsburg

June 28

PRODUCTION of steel continues at a rate of about 39,000,000 gross tons a year, against rates of about 35,000,000 tons on April 1, when the coal strike started, and 20,000,000 tons last December. While production is almost stationary, the trend is upwards rather than downwards, a very significant thing, seeing that the coal strike has now lasted almost three months and the steel industry can still function. Indeed, one observes no signs of uneasiness among steel manufacturers as to their ability to continue operating and complete their orders, even though they are on the whole, pretty well booked up for the next couple of months or more.

The strike at the union coal mines had been fully expected for many months, while the non-union strikes, in the Connellsville and other districts, were unexpected. Hence if there were any restriction of production on account of the strikes in general, it should be looked for among consumers who were depending on non-union production, as the consumers of union coal knew perfectly well that their supplies were going to be shut off and that they must have stocks. There was, in fact, much stocking. Now the Carnegie Steel Co. normally operates its blast furnaces almost exclusively on Connellsville coke and by-product coke made from Connellsville coal, hence its experience is crucial. The Carnegie company has just blown in a third blast furnace at the Farrell works, furnishing the steel department enough pig iron to operate in full. This makes 38 Carnegie furnaces in blast, against 35 at the middle of May and 34 on April 1, when the coal strike started. Of course unusual expedients have been resorted to in accomplishing these results.

Steel Prices.—Not much change is to be noted in the week in the situation as to prices, but there are some slight changes. Bars, shapes and plates, which were occasionally going up to 1.80c., now generally find their maximum at 1.70c while the basis price of 1.60c remains. This is done by the Steel Corporation on such deliveries as it can make, usually far into the future, and occasionally by an independent. Early deliveries ordinarily obtainable only from independents, generally go at 1.65c or 1.70c.

Hoops and bands are firm at a minimum of 2.40c, it having been possible until quite recently to do 2.25c on attractive orders with the leading interests, while some small lots with undesirable specifications go at 2.50c. The hot rolled strip mills, which used to get more for their product than the hoop mills, but when prices were weak all around a few months ago were quoting below the hoop mills, are now above again, and have gotten 2.75c in some cases. Cold rolled strips remain at 3.75c by the American Steel & Wire Co. and 4.00c by the independents.

In the direction of stabilization of prices is the opening of sheet order books by the American Sheet & Tin Plate Co. (Steel Corporation) for August and September at old prices, the company's opening on June 2 having been for July only. Independents had been quoting, and securing in many cases, advanced prices, and most of them are disposed still to ask higher prices, believing that the leading interest will soon be sold out. The leading interest's prices are those made by the $3 a ton advance early in April, and are the lower of the prices following, the higher being the usual quotations of independents: Blue annealed sheets, 2.40c to 2.50c; black sheets, 3.15c to 3.30c; galvanized sheets, 4.15c to 4.30c. antomobile sheets, 4.50c to 4.75c. It is possible to obtain even 5.00c on prompt deliveries of automobile sheets, and some sales have been made at the price.

As to the coal strike, the strike is still on in full force at the union mines, except for various defections in West Virginia. In the non-union fields the strikes have been waning very slowly. In the Connellsville region men have been returning to work in larger numbers in the past fortnight than formerly, but production in the region is still far below the rate of last March and still farther below the capacity. Connellsville steam coal is a shade easier in the week, at $3.40 to $3.65 for mine-run.

Steel Market Prospects— While the steel mills are exhibiting no uneasiness as to their ability to continue production, despite the coal strike, and fill their orders, buyers of steel also exhibit a feeling of contentment and are not pressing to make further purchases for late deliveries, except in the case of new wants arising, involving steel for freight cars, buildings, bridges, etc. Buyers still show an eagerness to receive deliveries of steel already bought, and the mills are under considerable delivery pressure.

July and August, the "midsummer period" are always dull months in the steel market and as the period is now at hand the question is whether the lightness of demand in the open market is due to this seasonal condition or is a reflection of a general conclusion on the part of buyers that the coal strike is not to be feared after all. This question could be answered, probably, if there were complete and accurate information as to stocks of steel in buyers' hands. The deliveries are well known, as the rate of steel production from time to time has been known, but the rate of steel consumption has not been known. There is much talk on the subject of stocks of steel but hardly anything is known. Some observers insist that obviously the ultimate consumption of steel has been much less than the deliveries in the past four months, while mills rejoin that buyers can hardly have much steel or they would not be pressing for deliveries as they are.

Mills are well sold up at present, but it is plain that the steel market will have to make a new start after the summer dulness, and what kind of a market, in general, there will be in the Autumn will probably be disclosed at the outset according to whether sellers or buyers make the first move to resume business on an active scale. Meanwhile the situation is that buyers are well covered, so that things will run along for a few weeks without any change. The market will probably be quite dull in July and some may reason from this that the situation is weaker, but that will be a false showing.

Pig iron remains practically stagnant prices being largely nominal and unchanged at $25 for Bessemer and basic and $24 to $25 foundry, f. o. b. valley furnaces.

CONDITIONS IN NON-FERROUS MARKETS

SPEAKING to Ernest W. Knight, of Frankel Bros., Toronto, on the non-ferrous metal situation, he said that domestic copper is selling at not less than 13.87½c, with a great many producers holding to 14c. He mentioned that the immediate spot market seems to have all the copper required, but some interests have recently been testing the market for third and fourth quarter delivery.

Continuing, he said, "The foreign market is stronger and higher and would seem to indicate a brisk export business for July and August. It has not yet been recognized that Germany is the most important factor in export buying. More than half of the red metal exported from the port of New York during the current year, has gone to Germany. The May shipments of copper for Europe from the port of New York alone, were over 20,000 tons. There are likely to be increased prices in the immediate future, and I would recommend purchasing as early as possible for from 3 to 6 months ahead.

"The tin situation is extremely peculiar. In figuring the likelihood of an advance or decline in the price of tin, it must be remembered that by August, the tin plate manufacturers will have ceased their operations for several months and as soon as these works are closed down, lower prices will probably be the order of the day. On the other hand, it must be remembered that the bulk of the tin for tin plate operations is already purchased to cover the balance of the year.

"Mr. A. G. Glenister, chairman of the federated Malay States chamber of mines, in his address to a general meeting in Panang, some few weeks ago, stated definitely that the council, was opposed to a restriction of output. 'Such a policy,' he said, 'would raise prices and it would be very difficult to enforce. Moreover, any system which in-

volved an increase in unemployment, would not be advisable. From this it would appear as if tin is likely to remain at round about its present position until August or September, when a slight decline may be looked for.

Aluminum Situation

"Aluminum still remains firm and shows a tendency toward higher prices —particularly does this apply to sheet and wire. The electrical trades are still taking large quantities of cable, and the aluminum utensils business is snapping up practically all the sheet they can lay their hands on. No. 1 Virgin is now quoted at 20c, and the outside price has been advanced 1c per pound for all positions. The production of aluminum during the 12 months just passed, has shown a decrease of approximately $41,000,000.00 in comparison with the same period of last year. The market is firm and higher prices are likely to prevail in the near future.

"The nickle market is still stagnant and producers have enough on hand to take care of the demand for this year and next, if they do not mine another ounce. Spelter is firm with an upward tendency. An advance of 20c per 100 lbs. has taken place since last month's report, and stocks are being held at 5.25 East St. Louis for June shipment. There is every indication that this price may be increased in the immediate future. Buyers would do well to lay in stocks for at least 3 months ahead.

"Lead is also firm and likely to be higher. The market is held at round about 5.45 East St. Louis, which is an advance of 20c per 100 over the last figures. There is no likelihood of any decrease and buyers would be well advised to cover requirements for at least 3 months. A great many offers were recently made to purchase July supplies at 5.62 1/2, New York but the offers met with no response from sellers, 5.75 in carload lots, New York City, being demanded. Sales have been exceedingly heavy for this time of the year at the figures quoted.

"From the foregoing, it will be noted that the non-ferrous metals in general, show an increased activity, with the corresponding advance in price. Metals of all descriptions are cheap at to-day's figures."

PIG IRON PRODUCTION

May Figures at Lowest Level in Several Years

The production of pig iron during May declined to the lowest level which has been reached in several years. The tonnage was 23,363, representing a decrease of 9,209 tons from the April production. The record for the corresponding month last year was 56,091 tons. About 73% of the May production was foundry and malleable iron, intended for direct sale, while the remaining 27 per cent. chiefly basic iron was made for the use of the producing companies.

An interesting development was the increase in the output of ferro-alloys. The tonnage of 3,397 was the greatest since January, 1921, when, 3,941 tons were reported. The output was augmented by the 2,499 tons of spiegeleisen manufactured for further use. The remainder, comprising 181 tons made in blast furnaces and 717 tons principally 75 per cent. and 80 per cent. ferro-silicon manufactured in electric furnaces, was intended for direct sale.

FACTS OF BUSINESS SITUATION OF TO-DAY

BUSNIESS is better. The depression which began in the United States in 1920 and continued throughout 1921 has passed, and substantial progress has already been made toward normal activity and a new business cycle has been entered upon. Adverse conditions, as the coal strike, may temporarily retard the upward swing. Other factors, such as wide-spread crop failures, might even result in recession for a time, but no circumstances can alter the fact that there is now an unassailable basis for confidence in slow and steady expansion of the commercial and financial activities of this country.

"This basis for confidence is fivefold," continues Stevenson E. Ward, vice-president of the National Bank of Commerce, in Commerce Monthly. Here is how he divides the reason for confidence: First, there is plenty of money to be had at reasonable rates both for short-time and long-time requirements. Second, stocks of finished goods and of raw materials have been reduced to reasonable proportions. Third, commodity prices are stabilizing. Fourth, conditions in basic industries, including agriculture, are improving, and production is expanding. Fifth, gains are not confined to the United States. Conditions are improving throughout the world. Some countries constitute exceptions to this statement, but their bearing on the international situation is not great enough to alter the fact that the world outlook is better, with the United States and Canada in the forefront of improvement.

CHEMISTS CAN HELP PURCHASING AGENTS

WE WOULD like to call your attention to some of the ways in which we believe chemists can be of service to those supervising the purchasing of large organizations, writes J. T. Donald & Co., Montreal, chemical engineers, and consulting chemists. A great many materials sold to-day are subject to great differences in quality," they continue, "and in many instances these differences are only accurately estimated by chemical analysis. Further, although a cheaper article may appear to mean a saving, on carefully looking into the matter it is frequently found that the higher priced material is really the cheaper. As an example of this, take the case of coal. Some time ago we received two samples of coal showing the following analyses and prices, f. o. b., Montreal.

	Moisture	Ash	B. T. U.	Price
No. 1.—	2%	10%	13,000	$9.50
No. 2.—	2%	5%	14,000	$10.25

"In the case of the better grade coal No. 2, the price is $10.25 for 14,000 b. t. u. In the case of the lower grade coal the price is $\frac{\$9.50}{13,000} \times 14,000 = \$10.23$ for 14,000 B. t. u. or the two coals are approximately the same price. That is to say the cheaper coal costs just as much for the heating value received to use more of it and extra expense is incurred in freight, labor of unloading, firing, and labor in removing the extra ash, you will note that there is twice as much ash in the poorer coal as against the better coal. In other words, if your coal supply is 14 cars and you bought the poorer grade, it would be necessary for you to handle one more car of coal than if you bought the better grade of coal. The poorer the coal the larger these losses. Similar conditions exist in such materials as paints, oils, soaps, and other products too numerous to mention."

HEAVY EQUIPMENT FOR SEAMLESS STEEL TUBES

SINCE taking over the plant of the Welland Machine and Foundries for Lackawanna Tubes, Limited, L. R. Weeks, manager, has made several important changes. In the first place, the foundry which had been dormant for some time, has been placed in operation on jobbing work and, Mr. Weeks declares, is paying for itself. A machine shop 35x70, is being built, and this will also contain a galvanizing tank. The new order of things includes a building where coke will be kept under cover and an enclosure for pig iron, where a supply properly graded may be carried and easily handled.

The foundation of the main building, where the company will manufacture seamless steel tubing, has been completed. It provides for a building four hundred feet long and eighty feet wide, the height to the eaves being 27 feet with 21 feet of sash and a Robinson process roof.

The manufacture of seamless steel tubing calls for exceptionally heavy equipment. The prime machinery alone represents a total weight of 1,319,000 lbs. The reducing machine weighs 410,000 lbs. This is the machine that performs the main operation in the production of tubes to size.

Mr. Weeks expects that he will have the plant in operation by Sept 15. The outlook, he states, is exceptionally promising. This will be the first tube mill of its kind in Canada. The country's requirement in boiler tubes up to the present time has been imported, and it is stated that 1/5 of the quantities of the tubes imported in the course of a year would keep a mill busy 24 hours a day for a year.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—	
Silicon, 2.25% to 2.75%	29 15

News From the Industrial Field

Steel Bridge.—Joliceur & Veilleux Beauceville Co., Beauce, will construct a steel bridge at St. Malachie, Que., at a cost of $40,000.

The erection of several schools is being planned throughout the country. Following are a few of those contemplated: A high school to cost $32,000 will be built in Burnaby, B. C., McCarter & Naine, 509 Richmond St., Vancouver, architects. De Salles, P. Q., are going to erect a school, G. Gobel being the party to write to. Newmarket, Ont., is planning erection of school to cost $54,000. K. N. Robertson, is secretary-treasurer of board. The Toronto University is also planning to build a Forestry and Bottany building at a cost of $200,000. In the latter case Mr. Le Pan, superintendent of buildings, is the man to send correspondence to.

Dam to be built.—Plans are being prepared for a dam to cost $13,000 for Dominion government and provincial government. Port Haney, B. C., will be the site of the new dam.

Toronto, Ont.—The Architectural Bronze & Iron Works, Lansdowne Ave., have secured the steel sash and glazing contracts on the preparatory school building at Upper Canada College. This firm have also secured similar contracts on the Riverdale Technical School.

Toronto, Ont.—Tenders will be called shortly for re-building grain elevator, chutes and bins for Faramel Lt., Dupont St. The cost will be around $35,000.

The Ford Motor Co., Ford, Ont., are contemplating the erection of a new additional building.

The Canadian Aloxite Co., Montrose, Ont., have an addition made to their machine shop. The Robertson Construction Co., Niagara Falls, have secured general building contract.

The machinery used in new pulp mill at Three Rivers, will cost over $40,000. The Dominion Engineering Works, Lachine, have secured contract for the majority of work, while the Waterous Engine Works Co., Brantford, have secured contract for magazine grinder and all equipment for the same.

An electric lighting and power distribution system will soon be installed by Derby Township, Ont.

The Rockland Electric Light Co., is constructing an electric lighting system at Rockland, Ont., at a cost of $10,000. Another lighting system is contemplated at Yarmouth, N. S., and by the Yarmouth Light & Power Co.

Will Make Addition.—The collegiate institute at Galt will construct a new addition, which will cost approximately $335,000.

H. L. Burke has been appointed general superintendent in charge of the canal and river sections of the Queenstown-Chippewa power development.

The Carswell Construction Co., Toronto, has been incorporated as a limited company, with a capital of $100,000, and will continue to carry on a general contracting business.

According to reports, the Peter Lyall Construction Co., Montreal, have secured the contract for completion of sections 3 and 4 of the Welland Ship Canal. Representatives of the company are expected to take over the work shortly, which, up to a few weeks ago, was carried on under the cost-plus basis for the government. This should mean the employment of quite a number of men.

A glass factory to make all the glass used in Ford automobiles is to be built at Flat Rock, 23 miles south-west of Detroit, on Henry Ford's railroad, the Detroit, Toledo & Ironton, according to reports. The site has already been obtained and plans are now being drawn for the factory. A small part of the companies' glass is now being made at the River Rouge plant. It is planned to manufacture cement also at the Rouge plant, utilizing slag from the blast furnaces there. The plant, it is estimated, will cost one million dollars.

If gold output continues at anything like its present rate, more of this metal will be produced this year in British Columbia than during any year in the history of the province. In fact, the gold production of the entire dominion will be the greatest on record, even exceeding the output of the banner first year of the Yukon gold rush. The province of Ontario will be the main factor in the latter calculation.

Matachewan Power .Co., expect to have power available for distribution from the first unit of their Montreal River development by the end of the year. The first installation is being made at Indian Chutes.. A dam is to be constructed at Big Bend. Some 80 men are now working on the property and satisfactory progress is being made.

Request has been made to the federal authorities at Ottawa for the establishment of a government terminal elevator in Ontario. Toronto Harbor Commission, grain section Toronto Board of Trade, provincial Minister of Agriculture, and United Farmers of Ontario joined in making representations in support of this request, for which careful consideration is promised.

Reports state that a bill will be brought down in the house at Ottawa to permit the manufacture and importation or oleomargarine until August 31, 1923. This, if passed, means an extension of one year.

Production of portland cement during May 1922 was 11,176,000 barrels, which is the largest amount ever produced in any single month. However, the outstanding feature of the situation is disclosed by the indicated movement of cement, May shipments being in excess of any preceding month; and for the five months ending May 31 they were greater than during any similar period in past years. Shipments for the period were more than 5,000,000 barrels ahead of last year and nearly 4,000,000 barrels in excess of 1920 which was the largest year for the industry. The great demand is attributed to the record breaking proportions of the building boom which is under way and to increased municipal improvements. The construction of concrete pavements is also an important factor as the yardage under contract this year is greater than ever.

Montreal, Que.—Addressing the parliamentary committee of the League of Nations, Sir Charles Gordon, one of the Canadian delegates, stated that in volume of imports and exports Canada stood fourth among the thirty-four nations represented. In volume of commerce per head of population Canada stands first, and in export trade third, being exceeded only by Great Britain and France.

Three Rivers, P. Q.—It is expected that early in July the newsprint mill of the St. Maurice Lumber Company (a sibsidiary of the International Paper Company, of New York) will bring its fourth paper machine into operation and will then constitute one of the largest single paper mills on the North American continent, with a newsprint capacity of approximately 340 tons a day. The mill is also equipped with a wrapping machine capable of turning out 30 tons a day and has an excess of pulp production of some 200 tons.

Victoria, B. C.—Approximately $1,500,000 will be spent on highways in British Columbia this year, Hon. W. H. Sutherland, Minister of Public Works, announced. The work includes the Pacific Highway paving in the municipality of Surrey; the Nelson-Ymir road $80,000; Cascade-Rossland road $230,000; Similkameen district roadwork $80,000; Columbia Valley $62,000; Yellow Head Pass project $68,000, etc.

Vancouver, B. C.—A syndicate of British and California business men are organizing a ten million dollar undertaking which will be a holding and operating company of large British Columbia properties. It is to acquire the property and assets of the Masset Timber

Co., the Puget Sound Box Co., and the Western Marine Supply Co. The company will build and operate large sawmills and operate a large fleet of lumber-carrying ships. Many prominent men from both sides are behind the project.

Ford, Ont.—The Ford Motor Company of Canada, has been experiencing an active demand for its product. The company has maintained an almost uniform production of more than 200 cars a day since December, 1921, the greater part of the time turning out 225 a day, while from December, 1920, to December, 1921, production averaged about 150 a day. The increase in the current fiscal year, it is estimated, will bring the output near 60,000 cars, as against 46,832 for the preceding fiscal year, and 55 616 for the year ending July 31, 1920.

Ottawa, Ont.—Tenders for repairs to breakwaters at Port Colborne, Ont., are called for by the Department of Public Works and must be received by noon, July 4.

The Ottawa Public School Board, has accepted the bulk tender of the Gilmour Construction Co., amounting to $72,582 for the construction of an addition to the Kent Street school.

Ottawa, Ont.—The city council has awarded the following contracts for the civic hospital: plumbing and draining Garth Co., Montreal, $111,000; heating and ventilation W. G. Edge Lt., Ottawa, $105,581; electrical wiring, Fred Wilson, Ottawa, $33,527.

Plans for the construction of the big stadium of Ottawa Ltd., building are now complete. A site has been secured on King Edward avenue and building operations will commence as soon as possible. It is proposed to erect a building that will cost in the neighborhood of $300,000.

Ottawa, Ont.—An option on 33 feet of Queen Street property has been secured by M. J. Armstrong, machinist, who is shortly to erect a large modern machine shop on the site which is immediately west of the premises occupied by Just Motors. The property is 90 feet deep. It is estimated the new machine shop will cost in the neighborhood of $10,000.

T. P. Thompson, inspector of engines and boilers of steamboats, Kingston district, for the past thirty years, has resigned owing to ill-health.

The steamer Ferdinand of the Prescott-Ogdensburg Ferry Co., is undergoing repairs at the Cornwall drydock. She is being enlarged to carry at least two more automobiles to cope with extensive automobile traffic.

Willing to Trade.—Vancouver, B. C. —M. de Redon, president of a large coal mining company in French Indo-China, says the French colony will trade tis high grade anthracite coal for British Columbia lumber to a total of half a million tons a year.

Marysville, N. B.—It was announced at the annual meeting of the Canadian Cottons, Limited, that the company has at the present time 500 per cent. more orders than at the same time last year and sufficient to keep the mills fully occupied for the next four months.

Sydney, N. S.—Nineteen hundred men are now working at the Dominion Steel plant here, as against 1,200 at the first of May, according to information given out at British Empire Steel Corporation headquarters.

Walsh Plate and Structural Works of Drummondville, Que., have secured the contracts for steel on the following structures: New city hall and fire station, St. Guillaume, Que.,; college Immaculate Conception, Montreal; Riviere Rouge bridge, Valleyfield, Que.; extension to Montreal Cottons plant, Valleyfield, Que.; bridge at Bagot, Que.

The Steel Trough and Machine Co., of Tweed, Ont., are building two additions to their factory to take care of rapidly growing business. The firm has also established a Montreal office to supervise the work in Quebec and the Eastern provinces. Offices are also located in Toronto, Winnipeg and Vancouver.

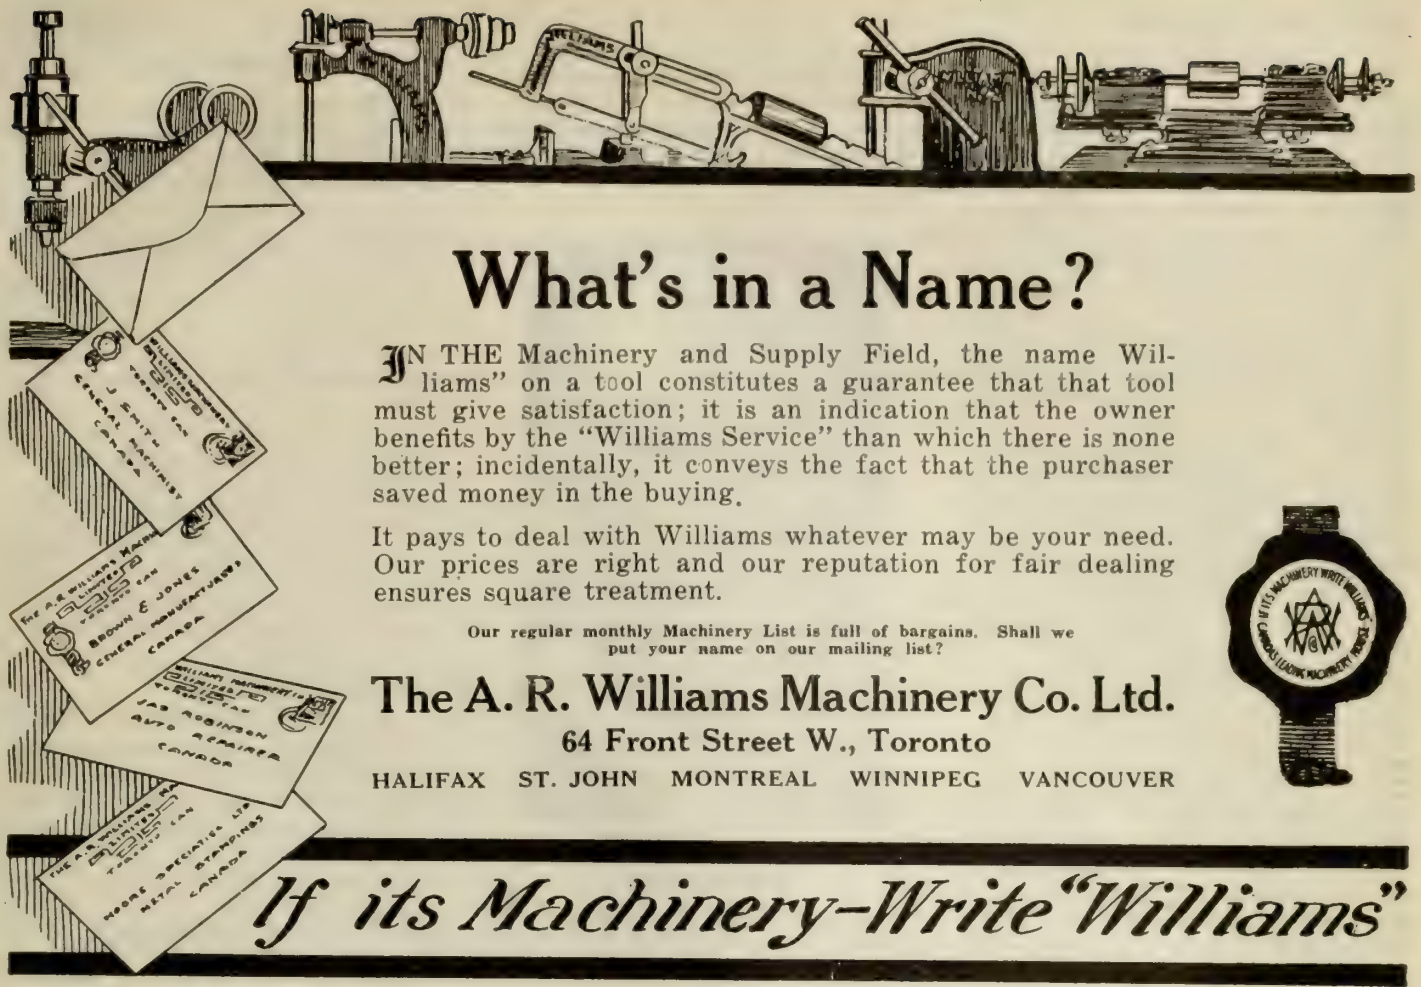
A company has been formed under the name of the A. D. Porter Mfg., Co., for the purpose of engaging in the production of pressed brass and steel goods for the plumbing, shoe and furniture trades. The company will commence operations soon in Galt, Ont., having acquired a building on Hobson street. The place is now being remodeled and machinery installed.

Supplies Ltd. of Kentville, N. S., are in the market for machinery to equip a small aerated water plant.

In an article on the development of Ontario's iron ore resources in The Northern Miner, the importance of iron as a factor in national development is emphasized. Among other important matters, the writer says:

"In 1921 the value of coal, iron ore and iron and steel products imported into Canada exceeded $356,000,000; which was about 80 per cent. of the value of the whole grain crop produced in the whole of Western Canada. During the last five years, the imports of iron and steel products into Canada aggregated $932,902,271, of which $896,372,209 came from the United States. With slight assistance from either the Ontario or Dominion Governments, our iron mines can be developed extensively and our iron and steel industry become the most important industry in Canada."

FINDS BUSINESS BETTER IN OTTAWA



A survey of the machinery and metal trades in the Ottawa district shows rather a contradictory state of affairs for, whereas trade in medium work appears to be "booming," trade in large work is decidedly quiet, and small work is sandwiched in between the two, being fairly good. Of these machine shops specializing in medium work which were visited, all report trade either good, improving, or excellent. McMullen Perkins Ltd., have been enjoying a big volume of business. This firm installed two new grinders and a new lathe last year but their business is such that they are putting in another new grinder and have taken on two extra hands. Mr. McMullen reports that even in the usually slack months of January and February the works were kept going at full capacity and that he was employing more men than at the busiest time last year. Armstrong & Co. is another firm in the booming category. Mr. Armstrong has recently taken on two extra hands and is putting in a new grinder, three more lathes, and a new milling machine, which, when installed, will call for the employment of an additional three men. This firm finds its present premises altogether too small for its growing business and, as already announced, has secured a site on which an up-to-date large machine shop will be erected at once.

Mr. Lawson, of T. Lawson & Sons declares business to be improving. He has increased his staff by two but says that as yet the volume of increased trade is not sufficient to warrant the installation of any new equipment. The Victoria Foundry reports business as quiet with no large contracts in sight. Business in supplies is rather above the average.

CANADA MAKES GOOD SHOWING IN GREAT BRITAIN

Official monthly returns for the first quarter of 1922 indicate that British imports of passenger cars, trucks, and chassis are again on the increase, writes W. H. Park, secretary to the trade commissioner at London, England. The total number of passenger cars and trucks imported during this period was 2,495, valued at £461,328; chassis numbered 2,370, valued at £479,009. During the corresponding quarter of 1921 the total number of passenger cars and trucks imported amounted to 2,914, valued at £681,156; but imported chassis numbered only 963, valued at £314,863. Canada ranked first as a source for the number of finished cars and fourth with respect to chassis. France ranked second with regard to both finished cars and chassis. Italy was third for finished cars and first for chassis, while the United States was fourth in finished cars and third in chassis. Germany also made a good showing, although imports from that country were rather irregular.

A total of 2,448 automobile licenses were issued by the Province of Manitoba license department up to the end of April this year, according to statistics made public. Dealers' licenses total 244, motorcycles 465, chauffeurs 2,394, sales representatives 171, and permits 3,642. Revenue for the department so far this year amounts to $394,104, it is stated.

What's in a Name?

IN THE Machinery and Supply Field, the name Williams" on a tool constitutes a guarantee that that tool must give satisfaction; it is an indication that the owner benefits by the "Williams Service" than which there is none better; incidentally, it conveys the fact that the purchaser saved money in the buying.

It pays to deal with Williams whatever may be your need. Our prices are right and our reputation for fair dealing ensures square treatment.

Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

The A. R. Williams Machinery Co. Ltd.

NEW PRESIDENT CHOSEN FOR C.M.A.

JOHN R. SHAW, vice-president and general manager of Canada Furniture Ltd., Woodstock, Ont., has been elected president of the Canadian Manufacturers' Association for the coming year.

C. Howard Smith, president of the Howard Smith Paper Mills, Montreal, has been elected first vice-president, while Henry Bertram, secretary-treasurer of John Bertram & Sons, Dundas, Ont., has been appointed second vice-president.

Other officers elected are as follows: Thomas Roden, Toronto, Ont., (re-elected), treasurer; John D. Palmer, Fredericton, chairman executive committee; Joseph Picard, Quebec, chairman tariff committee; W. S. Campbell, Toronto, chairman transportation committee; Arthur Hewitt, Toronto, chairman membership committee; J. C. McFarlane, Toronto, chairman legislation committee; W. C. Coulter, Toronto, chairman industrial relations committee; W. H. Miner, Granby, P. Q., chairman education committee; L. L. McMurray, Toronto, chairman commercial intelligence committee; J. F. M. Stewart, Toronto, chairman publishing committee.

John R. Shaw, the new president, is not only interested in the Canada Furniture Manufacturers, Ltd., but is also connected with many other companies as official or director including the Canadian Linderman Co., Canadian Austin Machinery Co., Hastings Furniture Co., Vancouver, B. C., Macey-Abell Co., Victoria, B. C.; Overland House Furniture Co., Winnipeg; Canada Spool and Bobbin Co., Ltd., Walkerton; Oxford Cobalt Silver Mining Co.; British National Assurance Co., Toronto; Toledo Bridge and Crane Co., Toledo, Ohio. Mr. Shaw was born in Bruce county, was educated at Walkerton High School, the University of Toronto, and Osgoode Hall. He practised law in Walkerton and Toronto and later organized Canada Furniture Manufacturers, Ltd. He is vice-president of the associated Children's Aid Societies of Ontario and a member of the board of trustees of Woodstock General Hospital.

JOHN R. SHAW
President C.M.A.

C. Howard Smith, the new first vice-president, was born in St. Johns, Que., and went into the paper business as a youth.

Henry Bertram, the second vice-president, was born in Dundas and was educated in Dundas public and high schools. He entered his father's business in 1871 and 15 years later became a partner. In 1901, he was made secretary-treasurer. He belongs to the Engineers' club, Ontario, of Toronto, and the Engineers' Club, Montreal. Mr. Bertram is a director of several companies.

According to the arrangement made, C. Howard Smith becomes president in 1923, while Henry Bertram will fill the president's chair in 1924.

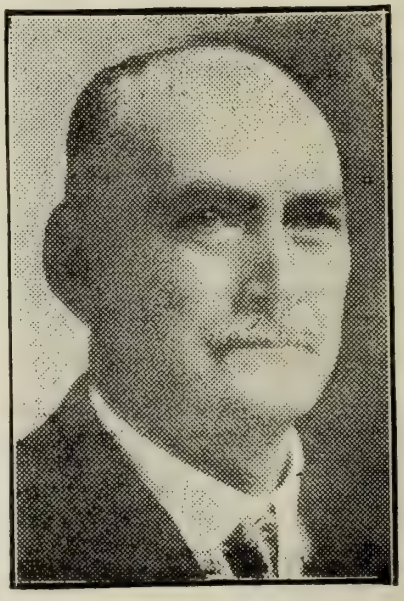
A shipment of 6,000 tons of Caucasian manganese ore has just arrived at Baltimore, said to be the first shipment from Russia since before the war. The manganese ore just brought in was ordered some time ago, and the transaction handled by Charles Hardy & Ruperti, Inc. Iron & Ore Corporation of America has since secured exclusive agency for output of the Caucasian mines.

The many friends of H. W. Petrie, Sr., president of the W. H. Petrie Machinery Co., Toronto, will have heard with regret of the death of Mrs. Petrie on Sunday last. The funeral was held from the family residence, 17 Heathdale Road, on Tuesday, June 27.

IMPORTANT EXTENSIONS DURANT MOTOR PLANT

Durant Motors of Canada Ltd., Toronto, in operation on the manufacture of motor cars since March 1, announce that they are planning the erection of extensive additions to their plant. They will include two new buildings, each 400 feet long, 100 feet wide and 6 stories high. Another building for crane and storage purposes, will be 500 feet long and one storey. These additions will more than double present capacity and it is expected will be completed by Jan. 1, 1923.

The first financial satement of the Company shows that $45,011.94 have been spent on land and buildings; $149,762.10 for machinery and equipment and $596,543.71 for materials and supplies for plant operations. The initial year's output of cars will approximate 25,000 with the demand showing some preference for the covered type of cars.



NEW AUTO FACTORY PLANNED FOR WINDSOR

If present plans go through Windsor, Ont., will have another automobile industry added to her already large list. The Windsor Steam Motors, have opened temporary offices at 6 London St., E, and intend producing a steam car. This company is a branch of the Trask-Detroit Steamer now producing a moderately priced steam car in Detroit.

H. B. Muir is president of the Canadian concern, and until the plant is ready, it is the intention to export machines from Detroit to take care of the Canadian market. Several claims are made for this type of steam car, one being that there are less than forty moving parts in the entire mechanism, and that either gasoline, kerosene or distillate can be burned.

Make it Snappy with a Jarvis

The Jarvis Self Opening Stud Setter is the Coming Tool

It is new
You May Not Have Heard of It, But You Will.

One of the first of these Stud Setters was demonstrated at the Indiana Factory of an Engine Builder. If you had seen it in operation, you would have said it was one of the snappiest jobs you had ever seen.

They were setting studs in Engine Blocks. The Stud Setter was put in an Air Chuck. A boy started the studs in the block by just a turn, to hold them.

The stop collar was slipped over the stud (this being the positive type Stud Setter). The Stud Setter was allowed to drop down on the stud.

Zip!

It was ready for the next stud.
There was no slowing down of the Air Chuck.

Tested for tightness, with a wrench, there was nothing for the wrench to do.

Tested for height, all studs showed an exactly uniform setting.

The Jarvis Self Opening Stud Setters, equipped with Morse Taper Shanks, are adapted for use on Drilling Machine, Air Drill, or Electric Drill.

They are made in two styles, Positive and Friction.

There are four sizes, Nos. 1-1/2, 2, 3 and 4.

Capacity: 0 to ½″
0 to ⅞″
0 to 1¼″
1″ to 2″

Simple in design.
Quick Grip and Ready Release.
Easy-working.
Jaws built for Long Service.
High Grade Material, Hardened and Thoroughly Tested.

Different size jaws may be supplied for any size stud within the capacity of each tool.

The Jarvis Stud Setters can be fitted to the Jarvis Quick Change Chucks.

Expensive?

Not a Bit of It. That is Another Interesting Feature. It has Everything Beaten in Price, Too.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN **CONNECTICUT**

Canadian Agents:

Williams & Wilson, Ltd. Montreal. The A. R. Williams Machinery Co., Ltd., Toronto, St. John, N.B., Halifax, N.S., Vancouver, B.C.

William A. Law, president of the First National Bank, discussing the business and financial outlook, says: "Hard work and plenty of it is bringing the world back to a normal basis."

Fort William, Ont.—John East and Co., contractors, have been awarded the contract for the erection of a high school building at Fort Francis. The amount of their tender was $62,700. R. E. Mason, of Fort William is the architect.

Fort William, Ont.—John East and the power-driven pulpwood loaded upon the south bank of the Mission river for the Detroit Sulphite company, is nearing completion and should be finished shortly. The construction involves an expenditure of $20.000.

Mr. Goodwin, of Ker & Goodwin Machine Co., Brantford, Ont., speaking to one of Canadian Machinery's representatives, said: "We have received an order for 54 oil engines from Quebec, and should complete this work in about six weeks' time." He also mentioned that business in general was much better.

Fort William, Ont.—It is estimated that $100,000 will be spent in the Fort William district this summer by the Nipigon prospecting company, in exploration work for oil. A test well down over five hundred feet on the Garver farm near Fort William, where good surface indications of oil have been found, will be completed, and a second well will be drilled at Squaw Bay.

T. A. Russell, well known in automotive and industrial circles has been appointed a director of Stewart Scully Co., a new investment house which opened up in Toronto a few days ago. J. F. M. Stewart, who is director in the Home Bank of Canada, Dominion Steel Corporation and other concerns, is to be president of the new firm which will speculate in real estate and high grade industrial issues.

Hamilton, Ont.—In spite of general depression and conservatism of action on the part of business men in 1921, Hamilton in that year added 24 new industries most of the newcomers being from the United States or British Isles. Six more have come to the city since the opening of the new year, and they now have nearly eight hundred industrial establishments covering in the activities a wide range of manufacture.

At the end of 1919, when the last industrial statistics were published, Hamilton had a total of 746 industrial plants, in which was invested a total of $165,500,399, giving employment to 30,293 people, receiving in salaries and wages the sum of $32,997,963, and accounting in that year for a production of $149,767,630 in value.

Although Samuel M. Vauclain, president of the Baldwin Locomotive Works, has denied that his company is seeking control of the Canadian Locomotive Co. there is still a possibility that a measure of control in the Canadian company may shift to interests closely associated with the American enterprise. We published last week a statement from W. Casey, president of the Canadian Co. at Kingston, to the effect there was nothing in the rumor, but while there have been no negotiations between the company and other interests tending to a change in control, it is known that a certain amount of stock has been taken up under option by American interests. The negotiations have been of a private character but as yet no transfer has taken place, but according to information, the option still holds good.

The Volta Manufacturing Co., Welland, Ontario, have recently booked an order from Renton & Fisher of the Hopetown Steel Works, Bathgate, Scotland, for one of their standard 3-ton capacity Heroult type electric steel furnaces, with transformer and switchboard equipment complete. This firm also build the "Duplex Voltage" or "Quick-Melting" type of furnaces for melting steel and grey iron, as well as three-phase furnaces, of an improved design, for melting brass, aluminum, etc. Some of their more recent developments include electric annealing furnaces, electric core baking ovens, electric babbitt heaters, electric water heaters, etc.

Toronto, Ont.—G. T. Pendrith, for 40 years a manufacturer of machinery supplies, died at his home a few days ago. Mr. Pendrith retired from business just a year ago, and made an unqualified success of his career. He came to Toronto from England when he was only ten years of age, and was in his sixty-fourth year when he died. He has always resided in Toronto since coming to Canada, and has been an active worker in various fraternal societies. He was a Pastmaster of Zeta Masonic Lodge, a Past First Principal of the Antiquity Royal Arch Chapter and a P. D. D. G. M. of Independent Oddfellows.

Imports of German goods into Great Britain during 1921 were valued at £20,550,000 nearly a third less than the total of £30,252,000 in the previous year. The value of British exports to Germany also declined from £21,707,000 in 1920 to £17,831,000 in 1921, while re-exports of foreign and colonial goods decreased in value from £29,382,000 to £22,897,000 Germany has been the most important factor in Great Britain's wool trade. During 1921, Germany was the destination for 116,409,000 pounds of British re-exports of raw wool, compared with 25,013,000 pounds in 1920, and 93,197,000 pounds in 1913, and in addition took seven million pounds of British home-grown wool.

Washington, D. C.—Sales of fabricated structural steel during May amounted to 82 per cent. of fabricating capacity, according to reports made to the department of commerce by firms comprising 70 per cent. of the fabricating capacity of the United States. The May business reported by 82 firms, having a capacity of 130,600 tons, totaled 106,620 tons as against April sales of these same firms amounting to 121,211 tons, or at the rate of 93 per cent. of capacity. Total sales throughout the United States, based on the reported percentage and a total capacity of 180,000 tons, amounted to 146,900 tons in May, while revised figures for April give a total of 165,900 tons. The April figures are based on reports from 87 firms, having a total capacity of 132,600 tons, whose sales amounted to 122,198 tons, or at the rate of 92 per cent. of capacity.

The Graham Nail Works, Toronto, are in the market for scrap ends of steel plate, 9, 10 and 11 gauge, carload lots or less.

Turpentine, owing to light supply and heavy demand, is credited this week with an advance of 15 cents the gallon.

Steel Pipe—The demand here shows the almost direct result of improvement in the building field. From Atlantic to the Pacific, industry then is well employed and prices on pipe are reported as tending upwards.

Ottawa.—Major T. E. Pooley, representing Vickers Ltd., of London, England, owners of a shipyard in Montreal, is in the Dominion for the purpose of looking over sites and conditions with a view to the establishment of branch factories. He is also investigating financial propositions, chiefly in Western Canada. He was in the capital during the week ending June 19 and met Premier King and several members of the house. He is now on his way to Vancouver, making stop-overs en route.

OVERCOMING HEAVY COSTS

(Continued from page 23)

the most of your belts and to safeguard against the possibility of a sudden shut-down in some department on account of belts going wrong, have all being overhauled periodically. Have greasy belts cleaned up. Have the spices looked over and the laps that have picked up carefully cemented down again. Have worn out belts cut down to a narrower width and use them over again. In this article we have briefly indicated several ways to keep belting equipment in trim. To summarize: Place a responsible man in complete charge of all transmission equipment; standardize belting as to type, brand, width and weight for every drive; demand regular inspection and reports as to condition of belts; run belting at a uniform tension and as slack as possible; eliminate injurious dressings and use a little good dressing; keep pulleys and belts clean and smooth; make sure that shafts and pulleys and belts are in constant alignment; overhaul belting periodically. If these suggestions are faithfully adhered to it will mean less power used, less work for mechanics and millwrights, uninterrupted operation of machines, increased output, lower cost of power transmission, and more profits for the firm.

ATKINS SAWS

METAL CUTTING

Present Conditions

Don't let present-day conditions worry you: everything is fundamentally sound. More economy is being called for, use

Atkins Metal Cutting Saws

Conditions are such that quality and quantity production is essential. The use of Atkins AAA Non-Breakable Hack Saw Blade and Frames, Circular Metal and Slitting Saws, Hot Saws, Cold Saws, Kwick-Kut Hack Saw Machines and Blades and Metal Band Saw Machines, will assure you of efficient, economical operation and give you quality and quantity production.

List of Directory of Dealers will be Found above Advertising Index

When answering advertisements kindly mention Canadian Machinery

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

MACHINE TOOLS, ETC.

Bertram & Sons, Ltd., John, Dundas, Ont.

The Canadian Fairbanks-Morse Co., Montreal, Que.

Garlock Machinery Ltd., Toronto.
